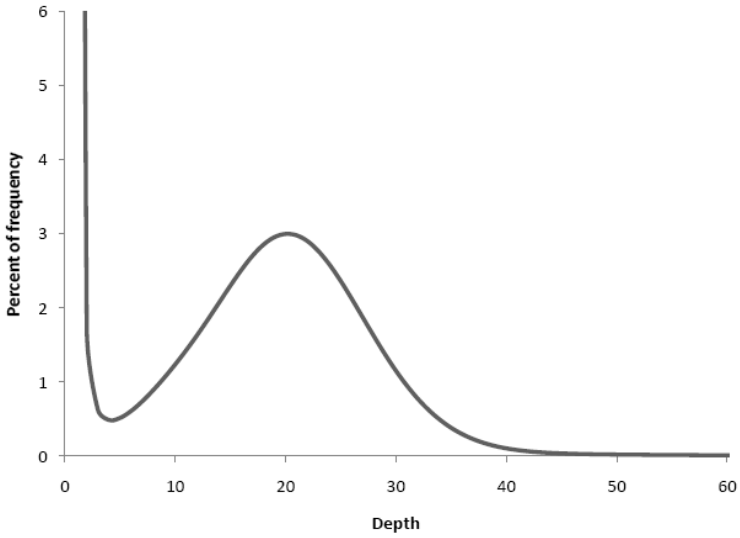
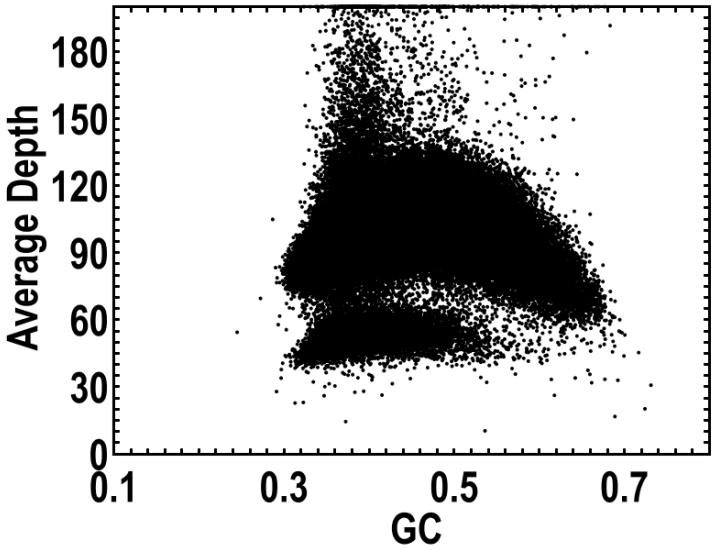
Supplementary Information

Supplementary Figures

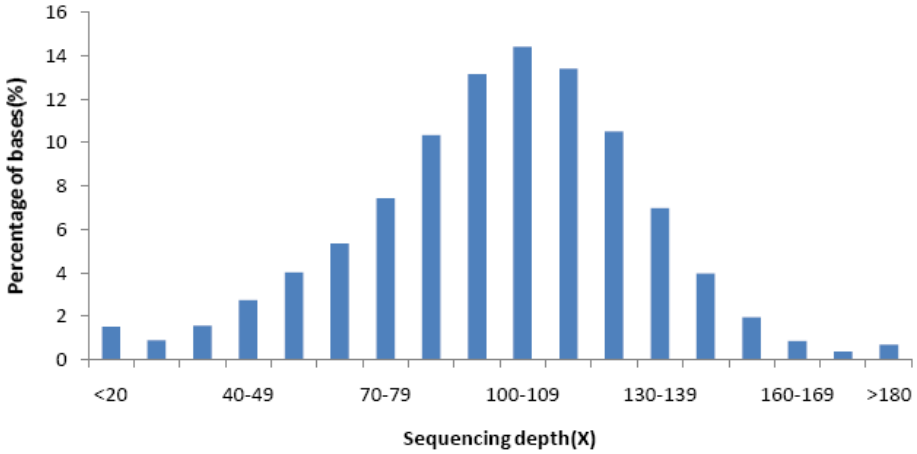
Supplementary Figure S1 | G-banded karyotype of the Amur tiger (TaeGeuk). There were no abnormalities in the chromosomes (2n=38).



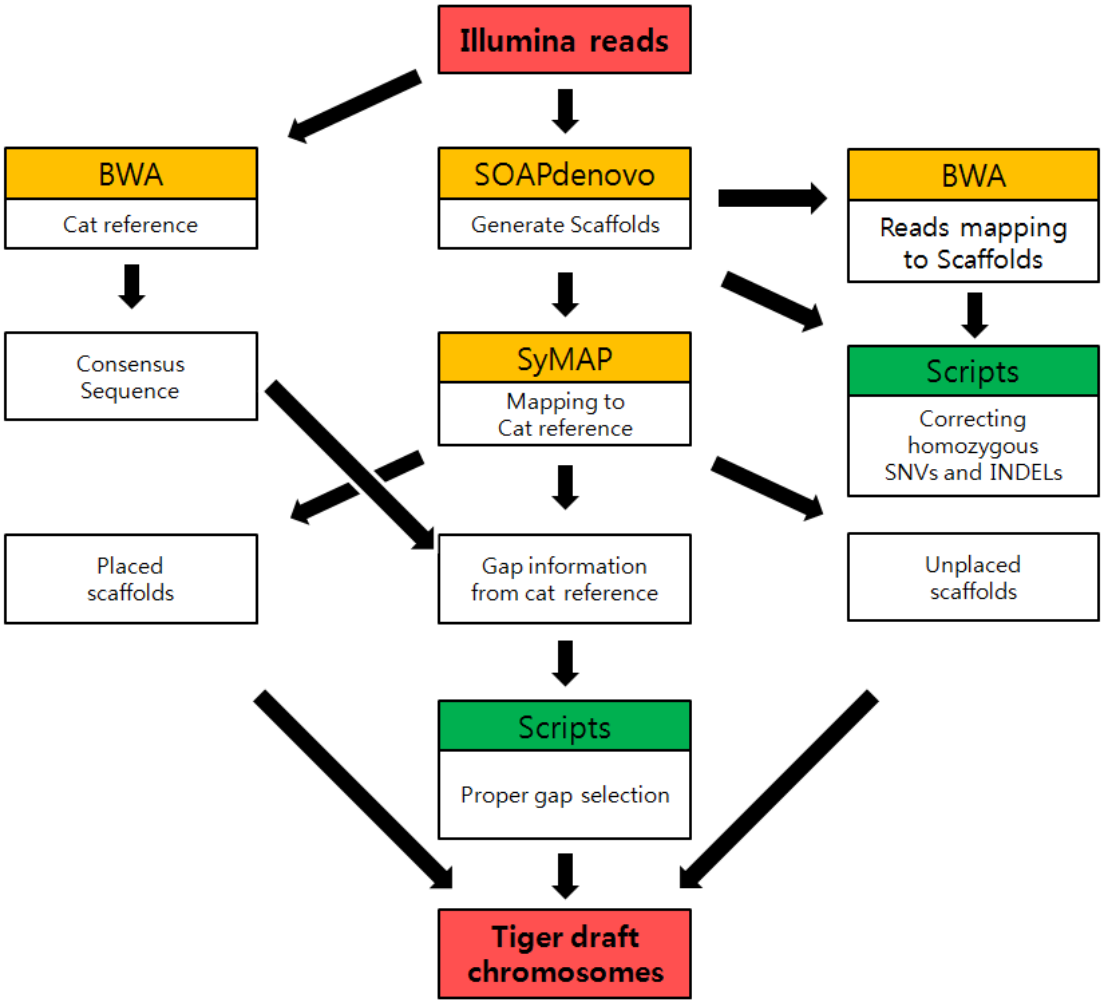
Supplementary Figure S2 | Estimation of genome size using 23-mers. The x-axis denotes the depth coverage of each unique 23-mer in the genome, and the y-axis denotes the occurrence of unique 23-mers within the sequence dataset. In other words, the x-axis represents depth, and the y-axis represents proportion, as calculated by the frequency at that depth divided by the total frequency at all depths.



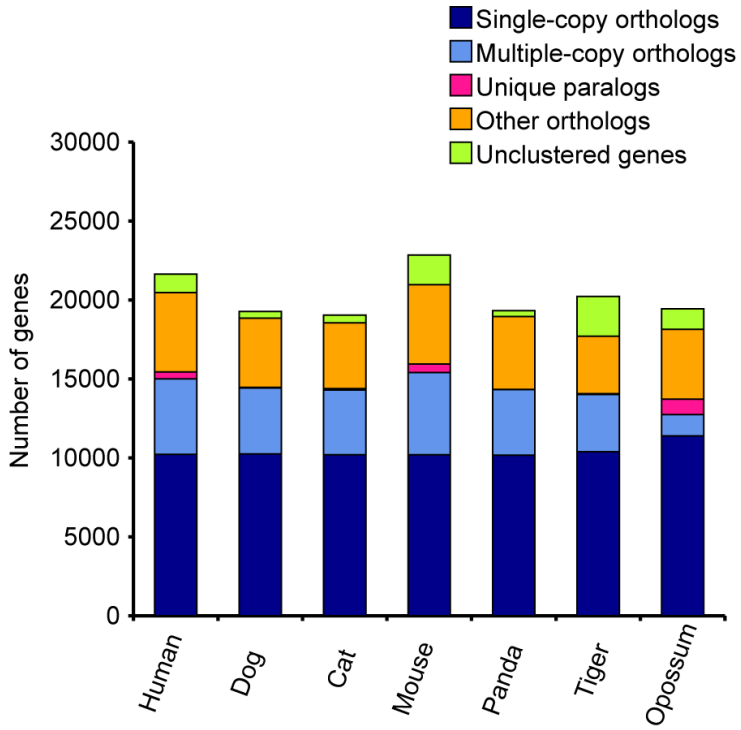
Supplementary Figure S3 | GC contents and sequencing depths. We used 10Kb non-overlapping sliding windows and calculated the GC content and average depth among these windows. To check whether the small block in the bottom of Supplementary Figure 4 originated from contamination from other species, some parts of the scaffolds were chosen from the small block and used as queries to perform BLAST with the nt library. The scaffolds were most closely related to chromosome X of *Felis catus*, which indicates that the small block represents chromosome X of the Amur tiger.



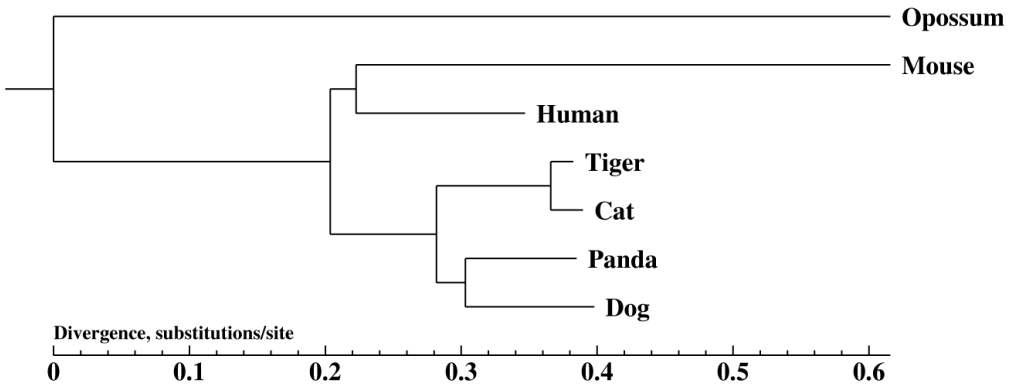
Supplementary Figure S4 | Sequencing depth distribution. Reads were aligned onto the assembled genome sequence using SOAP, allowing three mismatches for each read, and the frequency of each of the covered genome bases was calculated.



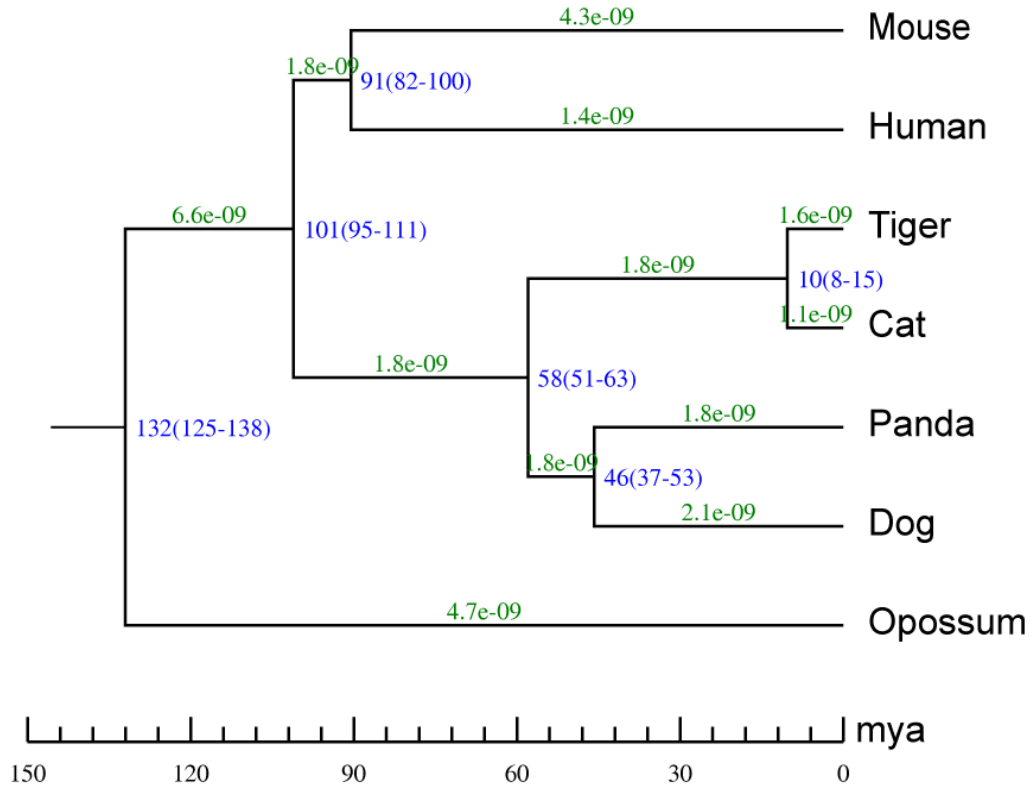
Supplementary Figure S5 | Amur tiger draft genome assembly pipeline showing the software used and the flow of sequence. As the Amur tiger genome is very similar to the cat reference genome, the chromosomal location and ordering information of the tiger scaffolds could be derived from the cat genome. The software and in-house scripts are shown in yellow and green, respectively. Consensus sequencce indicates continuous mapped regions, when the tiger short reads were aligned to the cat genome.



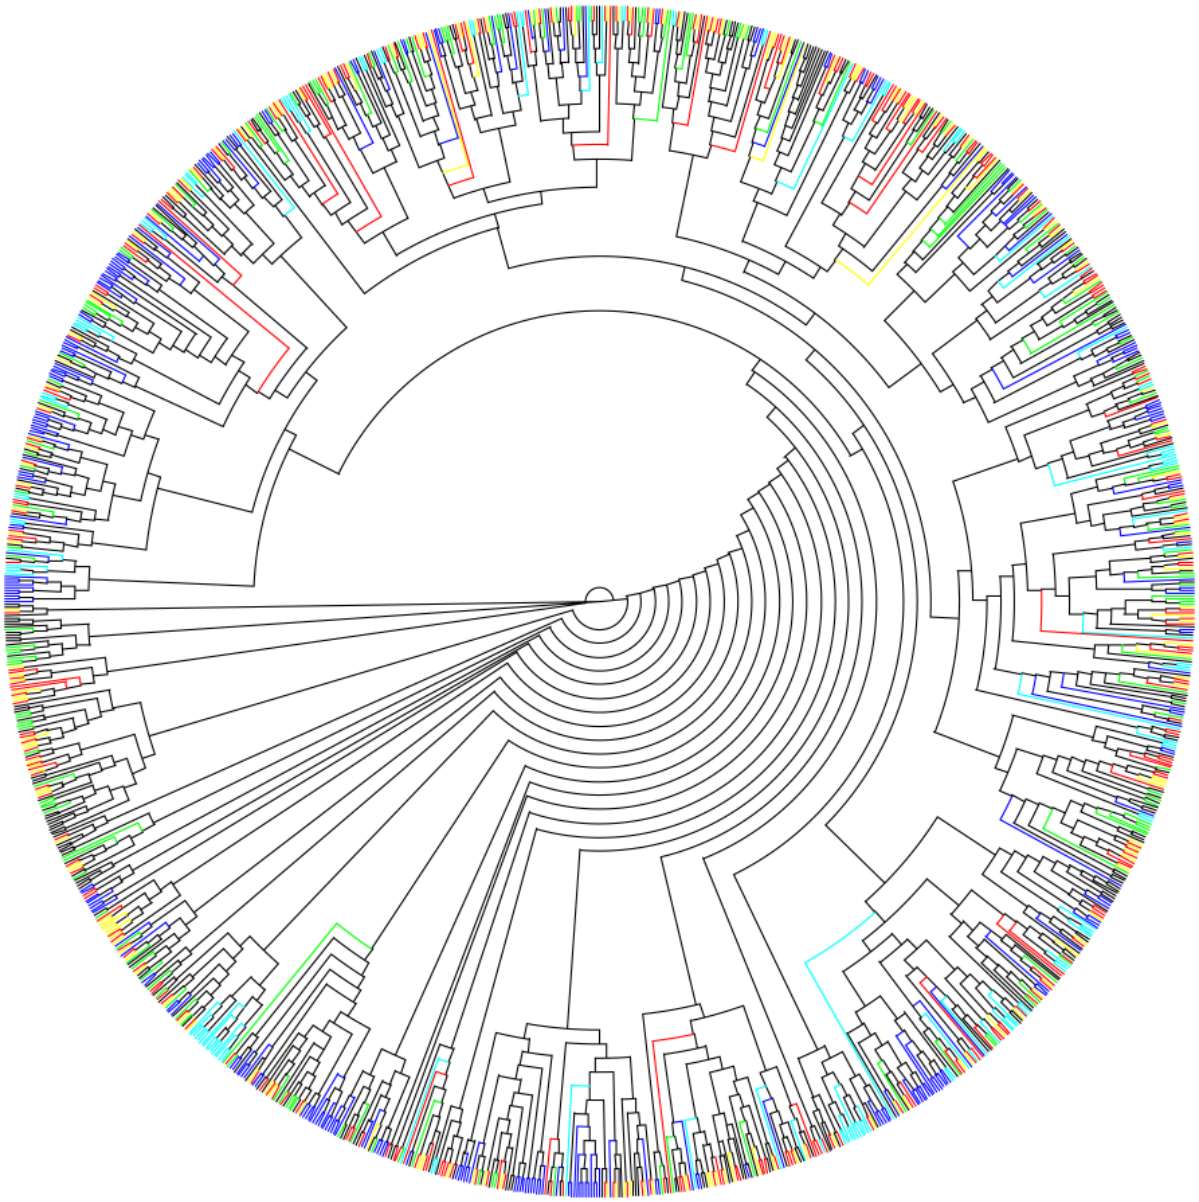
Supplementary Figure S6 | The composition of mammalian orthologous genes. A comparative account of ortholog and paralog genes in the Amur tiger genome is shown in comparison to the genomes of other seven animal species.



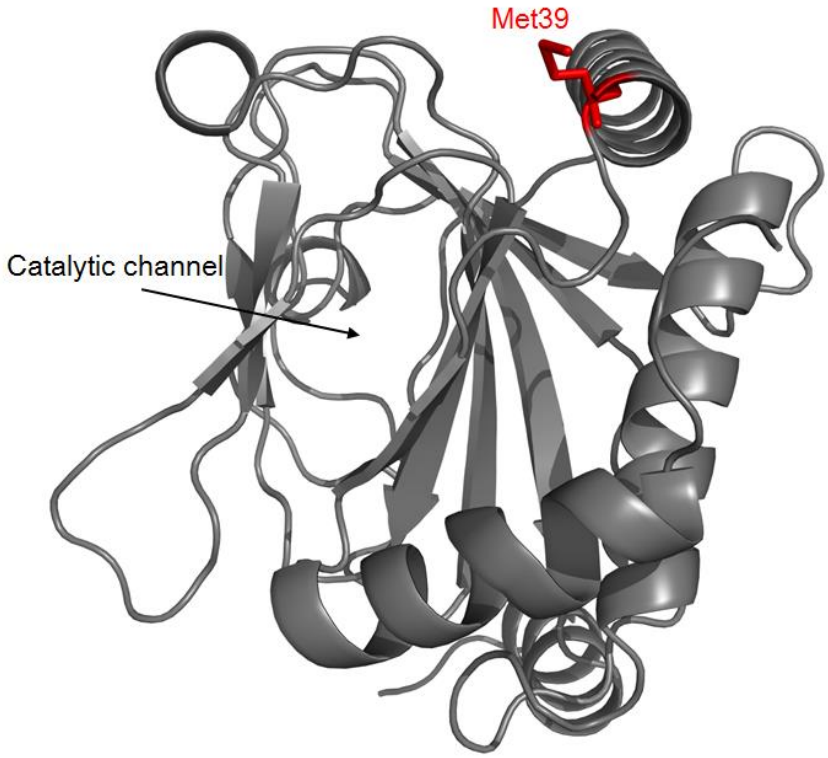
Supplementary Figure S7 | Phylogenetic tree constructed with orthologous genes on 4-fold degenerate sites. The branch length represents the neutral divergence rate.



Supplementary Figure S8 | Estimation of divergence time and substitution rate. The green numbers on the branches are the estimated substitution rate (substitutions per site per year). The blue numbers on the nodes are the divergence time from present (million years ago, Mya). The calibration times of (98.2 Mya) human-dog divergence and (57.5 Mya) cat-dog divergence were derived from the TimeTree database (http://www.timetree.org).

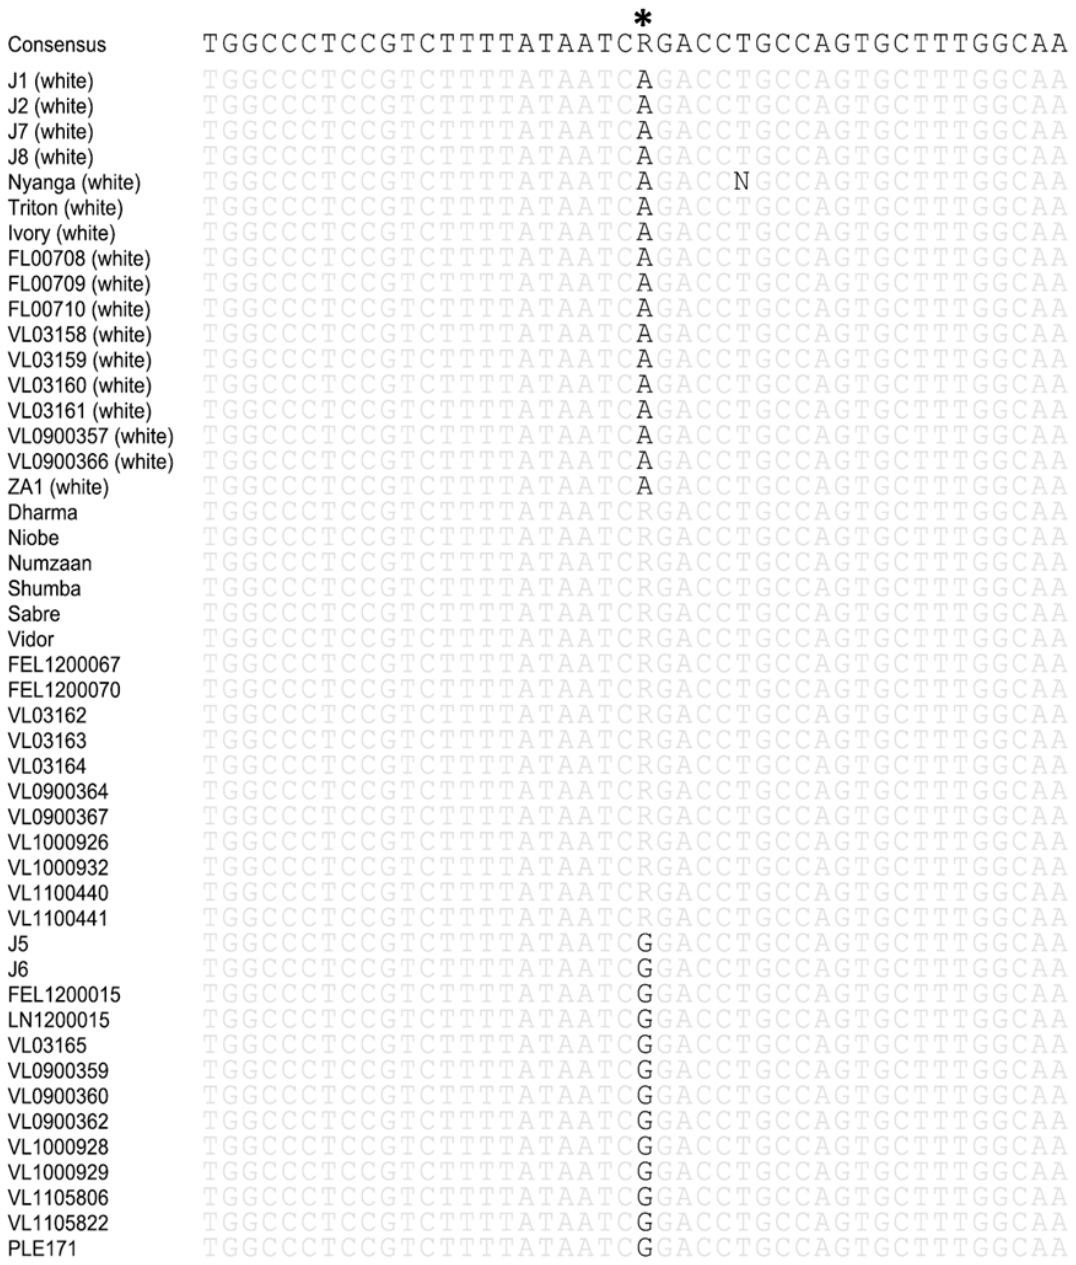


Supplementary Figure S9 | Olfactory receptor gene families expanded in tiger compared to domestic cat. Multiple sequence alignments and clustering were conducted using ClustalW2. Red, yellow, green, black, blue, magenta, and cyan edges in the outside are olfactory receptor genes of tiger, cat, dog, panda, mouse, human, and opossum, respectively.

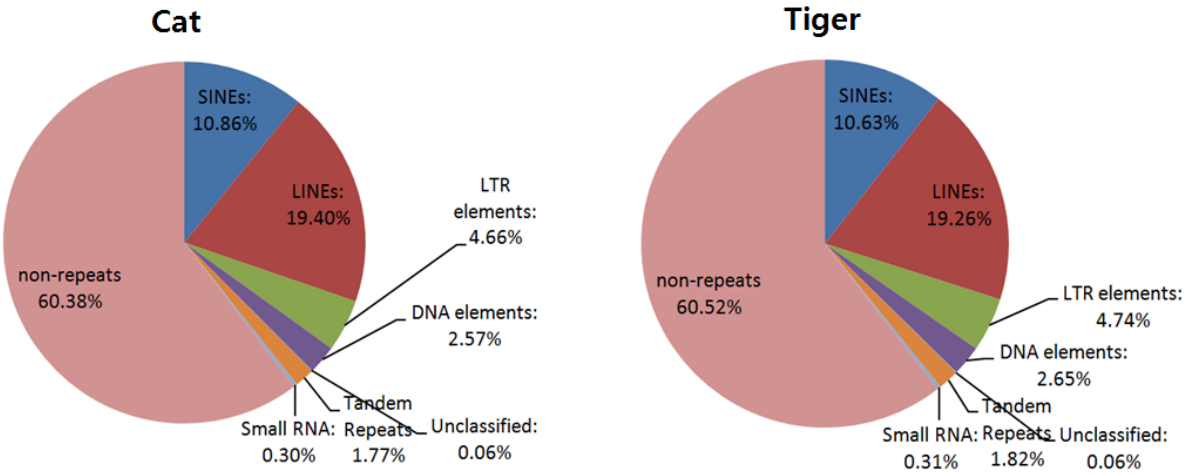


Supplementary Figure S10 | 3D position of snow leopard-specific amino acid change in the *EGLN1* gene. The red stick representation indicates the structural position for Met39>Lys39 amino acid change. The 3D structure was acquired from the Protein Data Bank (PDB) database (Entry: 3HQR).

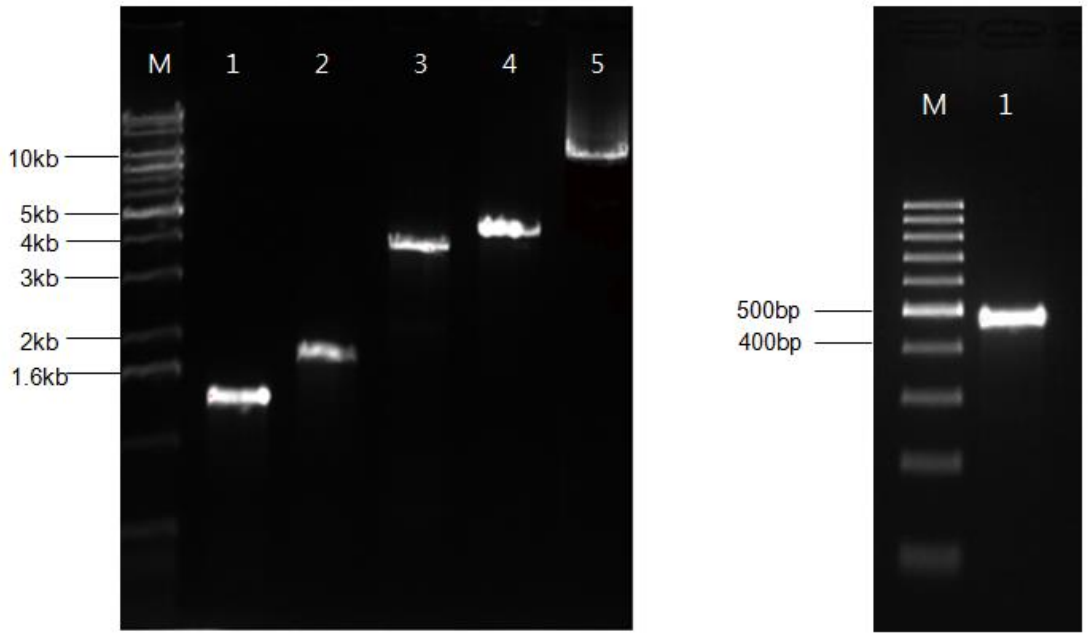
Supplementary Figure S11 | *EPAS1* mutations related to hypoxia in snow leopard. Non conserved amino acids in the big cats are shown in blue and red. The snow leopard-specific amino acids are Ile663 and Arg794.



Supplementary Figure S12 | Alignment of *TYR* exon 1 sequences from 47 lion samples. The *TYR*260G>A polymorphism (*) corresponded to the white lion phenotype. The figure represents a 44-nucleotide sequence of *TYR* exon 1 (base pairs 238-281). 'R' indicates the heterozygous nucleotide A/G.



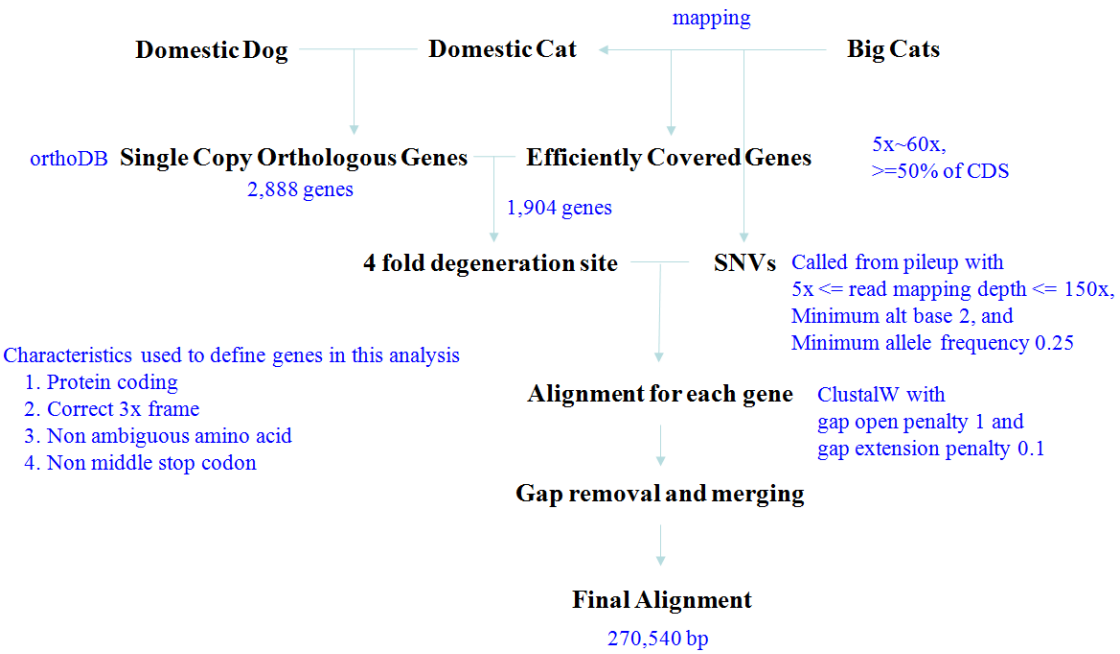
Supplementary Figure S13 | Comparison of repeats between Amur tiger and domestic cat (Felis_catus-6.2). The tiger and cat genomes showed very similar repeat compositions and ratios of repeat components. SINEs are short interspersed elements. LINEs are long interspersed elements. LTR is long terminal repeat.



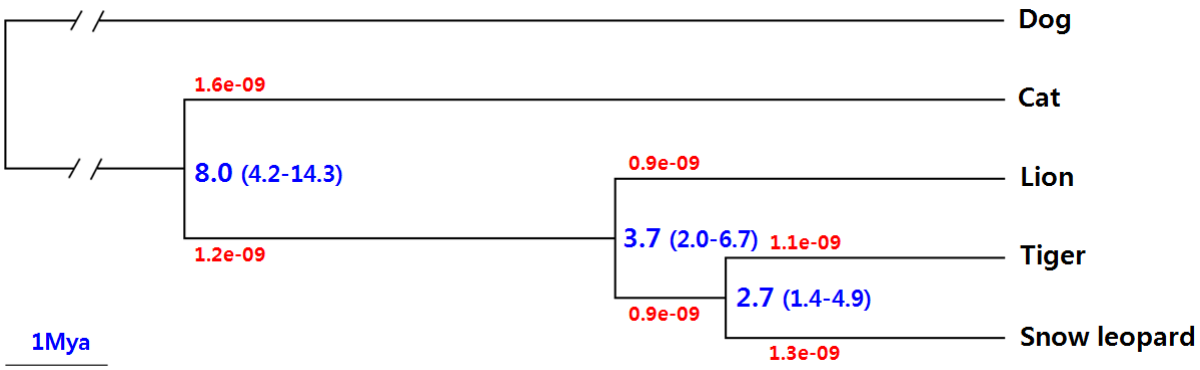
M : 1kb DNA extension ladder
1 : scaffold1490
2 : scaffold1545
3 : scaffold150
4 : scaffold402
5 : scaffold424

M : 100bp ladder
1 : scaffold309

Supplementary Figure S14 | Long range PCR results for tiger scaffold integrity validation. Six scaffolds having chromosomal rearrangements between the Amur tiger and domestic cat were validated by long range PCR experiments followed by the Sanger sequencing method. M Lanes are 1 Kb and 100bp DNA extension ladders. Other lanes are the target regions on each scaffold, supporting the tiger scaffold integrity and the six putative chromosomal rearrangements.

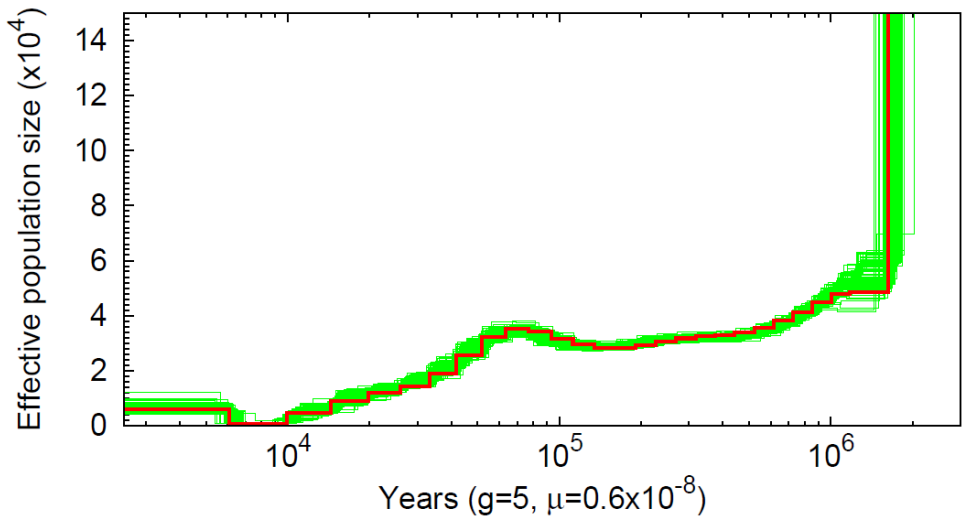


Supplementary Figure S15 | Data set selection for phylogenetic tree analysis among big cats. A total of 1,904 efficiently covered genes, which were extracted from orthologous genes between the domestic cat and dog and mapping results of big cat reads to the domestic cat genome (CAT.66), were used to construct the phylogenetic tree and to calculate the substitution rate of the big cats.

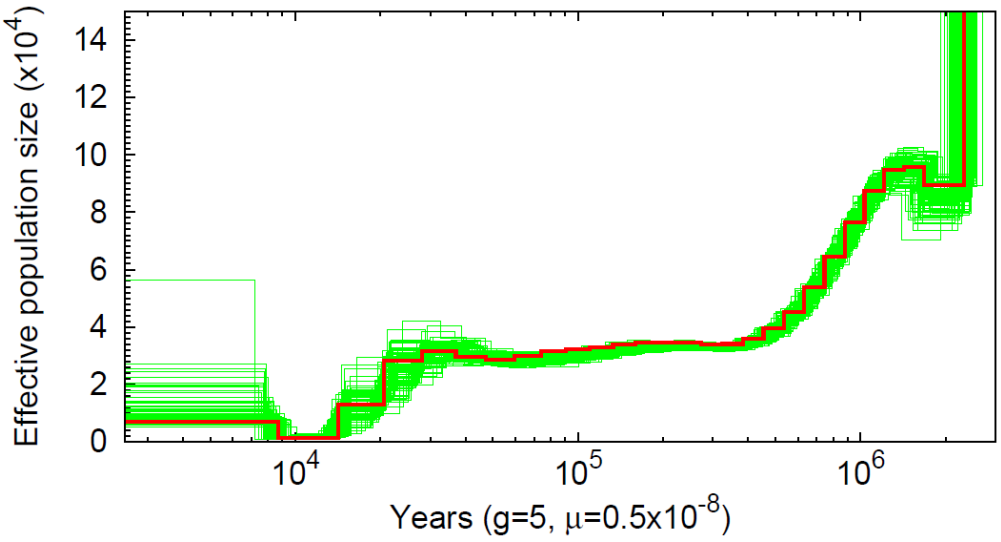


Supplementary Figure S16 | Divergence among domestic and big cats. Divergence times and substitution rates are shown in blue and red, respectively. The 95% confidence intervals of divergence time are shown in parentheses.

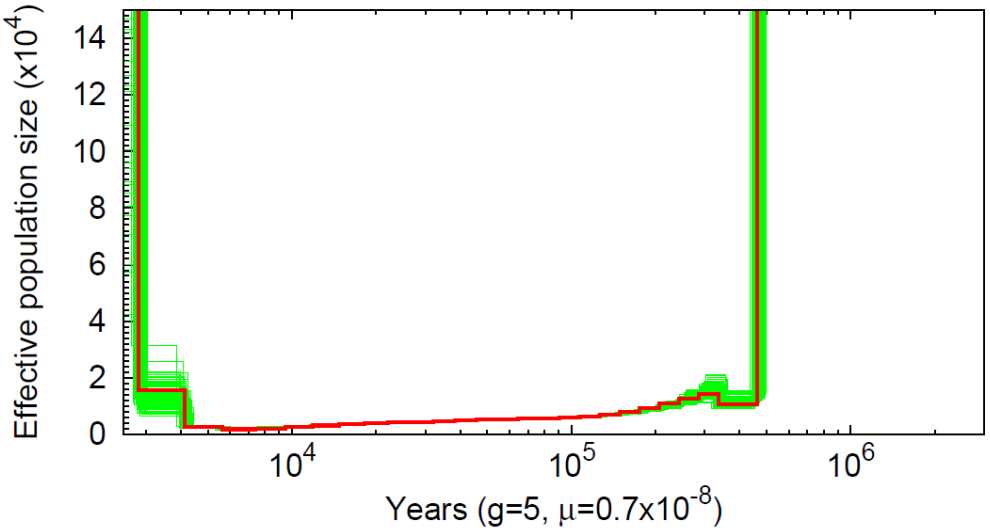
a. TG, μ = 1.1e-09 per site per year



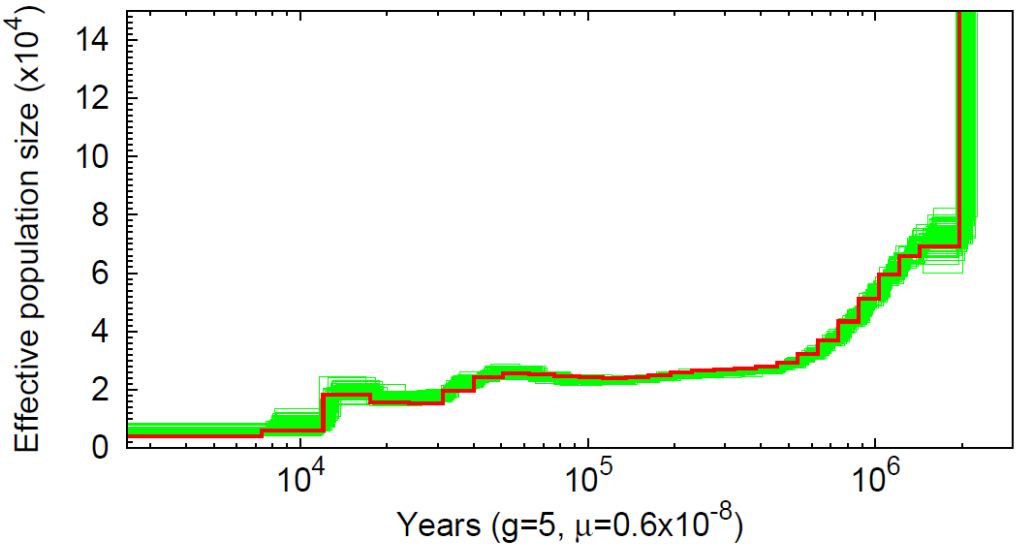
b. LN, μ = 0.9e-09 per site per year



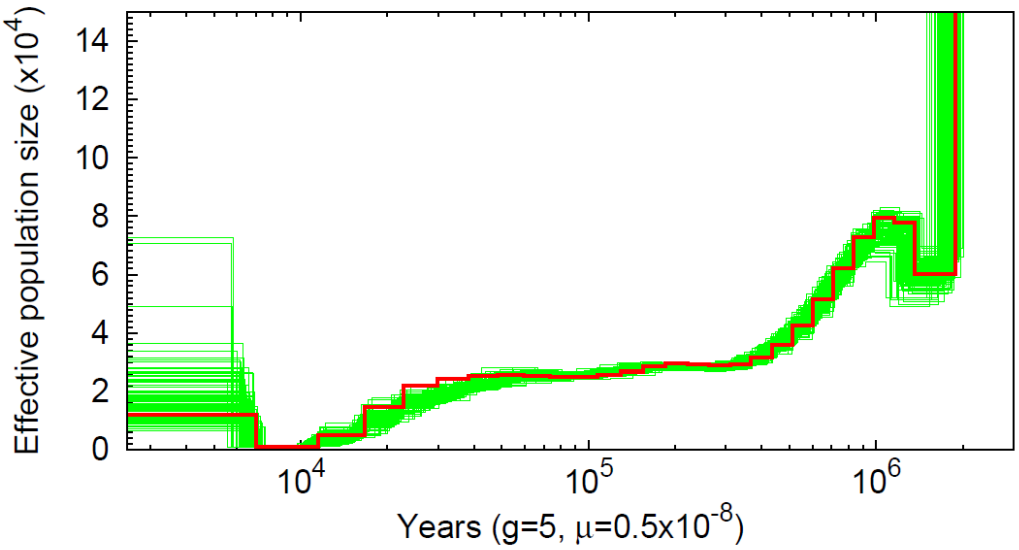
c. SL, μ = 1.3e-09 per site per year



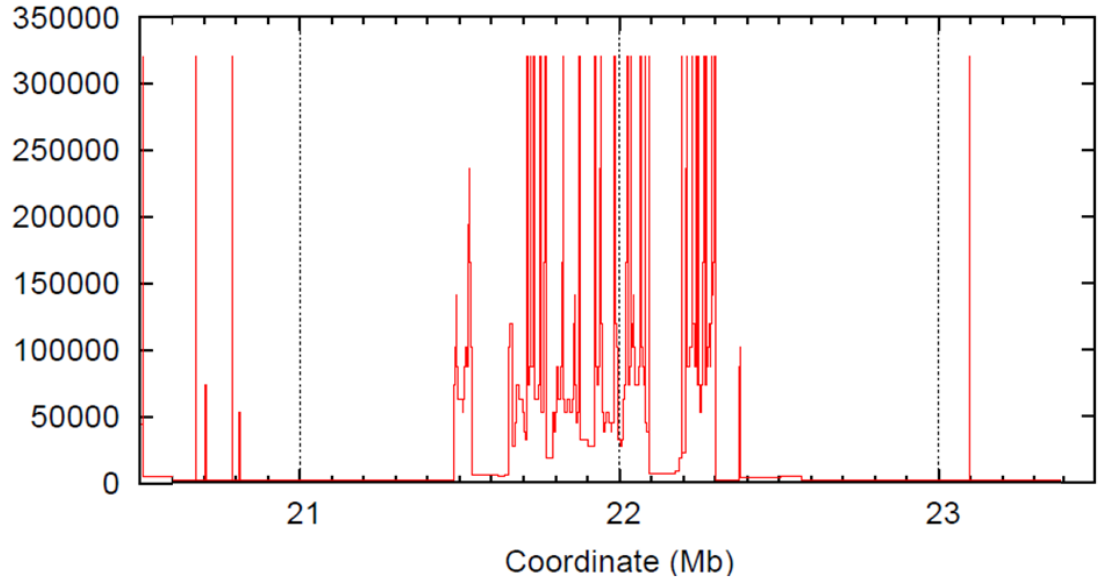
d. WTG, μ = 1.1e-09 per site per year



e. WLN, μ = 0.9e-09 per site per year



Supplementary Figure S17 | Population size history plots. μ of x-axis is mutation rate per generation which equals mutation rate per year multiplied by generation time (g, 5 years in this analysis). Red lines are population size history plots. The green lines indicate 100 bootstrapping results. TG, Amur tiger; LN, African lion; SL, snow leopard; WTG, white tiger; WLN, white African lion.



Supplementary Figure S18 | Sample plot of the most recent common ancestor distribution. X-axis represents chromosome coordinates. Y-axis shows the most recent common ancestor (TMRCA) of the corresponding region of the genome.

Supplementary Tables

Supplementary Table S1 | Sample characteristics

Sample	Name	Birth Date	Sex	Origin
Amur tiger	TaeGeuk	2003. 04. 01	Male	Russian Far East
White tiger	HwaRang	1999. 06. 18	Female	Bengal
African lion	SunDol	2007. 06. 22	Male	Sub-Sahara
White lion	SnowGirl	2005. 01. 18	Female	Sub-Sahara
Snow leopard	N/A	N/A	Female	West Mongolia

Supplementary Table S2 | Information regarding the seven libraries used for the tiger genome assembly

Paired-end libraries	Insert size	Total data (M)	Read length (bp)	Sequence coverage (X)	Physical coverage (X)
Illumina Reads	170bp	79418.44	100	32.55	27.67
	500bp	73543.91	100	30.14	75.35

cDNA		985	20,988	984	5.48	180	4,470
GLEAN		17,929	48,142	1,628	9.49	171	5,476
Synteny		16,907	38,144	1,598	9.66	165	4,220
Final		20,226	35,544	1,377	8.09	170	4,818

Supplementary Table S20 | Summary of evidence from GLEAN gene models

	≥20% overlap		≥50% overlap		≥80% overlap	
	Number	Percent (%)	Number	Percent (%)	Number	Percent (%)
P (single)	15	0.084	389	2.170	2,240	12.494
P (more)	2,193	12.232	2,388	13.319	2,603	14.518
H (single)	2	0.011	14	0.078	90	0.502
H (more)	4	0.022	39	0.218	367	2.047
C (single)	0	0	1	0.006	2	0.011
C (more)	0	0	0	0	0	0
P+H	15,118	84.321	14,608	81.477	11,895	66.345
P+C	10	0.056	12	0.067	19	0.106
H+C	11	0.061	18	0.100	29	0.162
P+H+C	556	3.101	372	2.075	239	1.333

P, *ab initio* prediction; H, homology-based; C, cDNA/EST expressed genes. According to the number of gene sources providing support, the evidence was further separated into single (one gene source) and multiple (two or more gene sources). The overlap threshold is relative to the CDS region of GLEAN genes.

Supplementary Table S21 | Statistics regarding domestic cat's predicted protein-coding genes

Gene set		Number	Average transcript length (bp)	Average CDS length (bp)	Average exon per gene	Average exon length (bp)	Average intron length (bp)
De novo	*AUGUSTUS*	20,563	50464.82	1440.33	8.88	162.17	6220.17
	GENSCAN	41,339	40403.16	1333.8	8.27	161.31	5375.22
Homolog	*H.sapiens*	26,628	32224.44	1566.59	8.8	178.04	3930.94
	C.familiaris	25,693	26239.48	1486	8.48	175.23	3309.23
	B.taurus	24,847	27404.2	1506.94	8.41	179.15	3494.1
Final		19,048	36841.82	1600.06	9.28	172.35	4254.37

The average transcript lengths do not contain UTR. Three approaches were employed in gene prediction: Homolog (*H.sapiens*, *C.familiaris* and *B.taurus*), *De novo* (*GENSCAN*, *AUGUSTUS*).

Supplementary Table S22 | Summary of evidence for the domestic cat's final gene models

	≥20% overlap		≥50% overlap		≥80% overlap	
	Number	Percent (%)	Number	Percent (%)	Number	Percent (%)
P (single)	574	3.01	771	4.05	911	4.78
P (more)	364	1.91	181	0.95	45	0.24

Supplementary Table S33 | Pathway analysis for big cat-specific genes having functional changes

KEGG pathway	Genes having functional changes	P-value
Propanoate metabolism	ACSS1,SUCLG2,MLYCD,EHHADH,ABAT,ACACB,HADHA,ALDH3A2	0.000032
Inositol phosphate metabolism	CDIPT,PIK3C2G,IMPA1,PIP5KL1,PIK3C2A,INPP5J,PLCG2,INPP4B,PIP5K1A,INPP5B	0.000092
Phosphatidylinositol signaling system	CDIPT,PIK3C2G,IMPA1,PIK3C2A,INPP5J,PLCG2,INPP4B,PIP5K1A,INPP5B,PIK3R2	0.00017
Histidine metabolism	DDC,ABP1,HDC,ALDH1A3,HAL,ALDH3A2	0.000242
Fatty acid metabolism	ACADVL,CPT2,ACADS,EHHADH,ACADL,HADHA,ALDH3A2,ACSBG1	0.000384
beta-Alanine metabolism	MLYCD,EHHADH,ALDH1A3,ABAT,HADHA,ALDH3A2	0.000775
alpha-Linolenic acid metabolism	PLB1,PLA2G4E	0.002141
mTOR signaling pathway	EIF4B,TSC1,STK11,ULK2,EIF4E2,PIK3R2,DDIT4	0.00242
mRNA surveillance pathway	PPP2R1B,SYMPK,UPF2,CSTF2,SMG6,RNPS1,NXF1,CASC3,CPSF1,DAZAP1	0.002569
Glycerophospholipid metabolism	ACHE,CDIPT,PLB1,PPAP2C,AGPAT9,LYPLA1,AGPAT4,PLA2G4E,AGPAT2	0.002654
Butanoate metabolism	ALDH5A1,ACADS,EHHADH,ABAT,HADHA	0.003381
Adipocytokine signaling pathway	IRS4,PRKCQ,STK11,LEPR,PRKAG1,PRKAG2,ACACB,IRS1,AGRP,ACSBG1,TRADD	0.005188
Nicotinate and nicotinamide metabolism	NNT,BST1,NT5C2,NAPRT1	0.005768
Biotin metabolism	HLCS	0.006898
Valine, leucine and isoleucine biosynthesis	LARS2,IARS2	0.00943
Selenocompound metabolism	SEPSECS,TXNRD2,MARS2	0.009687
Base excision repair	LIG1,NEIL2,NEIL1,MBD4,XRCC1,SMUG1	0.009855
Insulin signaling pathway	IRS4,PRKCZ,EXOC7,PRKAG1,PRKAG2,PDE3A,ACACB,IRS1,PYGM,TSC1,SHC1,TRIP10, EIF4E2,PIK3R2	0.011139
Lysine degradation	DLST,EHHADH,TMLHE,MLL3,NSD1,HADHA,ALDH3A2	0.011253
Glycerolipid metabolism	GK2,PPAP2C,AGPAT9,AGPAT4,AGPAT2,ALDH3A2	0.011846
Phenylalanine metabolism	DDC,ALDH1A3,PAH	0.013593
Ether lipid metabolism	PLB1,PPAP2C,PLA2G4E	0.018371
RNA transport	UPF2,RNPS1,NXF1,CASC3,EIF4B,EIF3D,NUP62,POP1,DDX20,TGS1,EIF2B2,EIF2B3,EIF4E2, GEMIN5,EIF2B5,NUP210L	0.021246
Fat digestion and absorption	APOA4,PPAP2C,PLA2G4E,AGPAT2,MTTP	0.024835
SNARE interactions in vesicular transport	SNAP29,STX2,VAMP7,USE1,GOSR1	0.024835
VEGF signaling pathway	PLCG2,SPHK1,NFATC4,MAPKAPK2,PLA2G4E,PIK3R2	0.026286
ABC transporters	ABCB9,ABCB8,ABCB10,ABCC8,ABCB6,ABCG4,ABCA5	0.026381
Aminoacyl-tRNA biosynthesis	SEPSECS,MARS2,EPRS,LARS2,IARS2,AARS2,MTFMT	0.029849
Sulfur relay system	TST,NFS1	0.032811
Linoleic acid metabolism	PLB1,PLA2G4E	0.032811
Valine, leucine and isoleucine degradation	ACADS,EHHADH,BCKDHB,ABAT,HADHA,ALDH3A2	0.034466
Fc gamma R-mediated phagocytosis	DNM1L,PPAP2C,PLCG2,SPHK1,PIP5K1A,PRKCE,PLA2G4E,PIK3R2	0.035663
Thiamine metabolism	NFS1	0.036962
Cysteine and methionine metabolism	TST,DNMT3A,BHMT,AHCYL2	0.037283
Folate biosynthesis	GGH,FPGS	0.044049
Nucleotide excision repair	RPA1,ERCC6,XPC,LIG1,ERCC4,ERCC1	0.04418
PPAR signaling pathway	ACOX2,SLC27A1,CPT2,GK2,EHHADH,ACADL,CYP8B1,ACSBG1	0.048026

Supplementary Table S34 | Pathway analysis for feline-specific genes having functional changes

KEGG pathway	Genes having functional changes	P-value
ECM-receptor interaction	ITGB7,ITGA3,RELN,SV2A,THBS3	0.000742
Inositol phosphate metabolism	PIK3C2B,PLCD1,INPP4B	0.002649
Phosphatidylinositol signaling system	PIK3C2B,PLCD1,INPP4B	0.003373
Focal adhesion	ITGB7,GSK3B,ITGA3,SHC1,RELN,BIRC3,THBS3	0.004653
Primary immunodeficiency	JAK3,ADA,BLNK	0.004695
Endocytosis	RABEP1,AP2A1,PDCD6IP,PSD2,ARAP1,DNM2	0.017982
Endocrine and other factor-regulated calcium reabsorption	AP2A1,DNM2	0.018888
Sphingolipid metabolism	GALC,SMPD3	0.020693
Pentose and glucuronate interconversions	DCXR	0.022482
Pathogenic Escherichia coli infection	TUBA4A,ABL1	0.022589
Amino sugar and nucleotide sugar metabolism	PGM3,UXS1	0.026656
Glycosphingolipid biosynthesis - ganglio series	ST6GALNAC6	0.030216
Hedgehog signaling pathway	GSK3B,GLI3	0.03109
ErbB signaling pathway	GSK3B,SHC1,ABL1	0.031777
Viral myocarditis	MYH11,ABL1	0.033443
Lysine degradation	PLOD3,SETD1A	0.03842
Melanogenesis	EP300,ADCY7,GSK3B	0.038865
Basal cell carcinoma	GSK3B,GLI3	0.041043
Collecting duct acid secretion	SLC12A7	0.043466
Pentose phosphate pathway	H6PD	0.043466
Pathways in cancer	FGF18,EP300,GSK3B,ITGA3,BIRC3,ABL1,GLI3,RALGDS	0.048299

Supplementary Table S35 | Statistical orthologous gene numbers

Species	orthologous gene numbers
Tiger:Cat:Human	7,415
Shared with Mouse	6,155
Shared with Dog	6,365
Shared with Panda	6,062

Note: Genes were required to fall into regions of large scale synteny between genomes, and to have completely aligned coding regions of human annotation, not to have frame-shift indels or altered gene structures, and not to show signs of recent duplication.

Supplementary Table S36 | Pathway analysis using positively selected genes

KEGG pathway	P-value	Positively selected genes
Endocrine and other factor-regulated calcium reabsorption	0.000421	AP2A2,PLCB4,CLTB
Drug metabolism - cytochrome P450	0.001581	FMO1,CYP2D6
Carbohydrate digestion and absorption	0.002447	PIK3CB,HK2
Acute myeloid leukemia	0.002468	PIK3CB,PML,RPS6KB2
Bacterial invasion of epithelial cells	0.002673	CLTB,PIK3CB,ARHGAP10
Nitrogen metabolism	0.005284	CA9,CA5A
Inositol phosphate metabolism	0.006009	PLCB4,PIK3CB
mTOR signaling pathway	0.006009	PIK3CB,RPS6KB2
Phosphatidylinositol signaling system	0.007212	PLCB4,PIK3CB
Type II diabetes mellitus	0.007863	PIK3CB,HK2
Amoebiasis	0.009544	PLCB4,ACTN4,PIK3CB
Arrhythmogenic right ventricular cardiomyopathy (ARVC)	0.010047	ACTN4,DSG2,ITGA2B
Insulin signaling pathway	0.016048	PIK3CB,HK2,RPS6KB2
Systemic lupus erythematosus	0.016285	HIST1H4L,HIST1H4K,ACTN4
Hypertrophic cardiomyopathy (HCM)	0.016749	MYH7,TPM4,ITGA2B
Cytosolic DNA-sensing pathway	0.020658	TREX1,ZBP1
Dilated cardiomyopathy	0.02136	MYH7,TPM4,ITGA2B
Calcium signaling pathway	0.022762	SLC8A3,PLCB4,TNNC2,PTAFR
Olfactory transduction	0.023162	OR2A1,OR7C1,OR10Q1,OR1J4
TGF-beta signaling pathway	0.026948	RPS6KB2,TFDP1
Endocytosis	0.027812	AP2A2,RAB11FIP3,CLTB,PML
Fc gamma R-mediated phagocytosis	0.031161	PIK3CB,RPS6KB2
ErbB signaling pathway	0.040566	PIK3CB,RPS6KB2
Cardiac muscle contraction	0.042259	MYH7,TPM4

Supplementary Table S37 | Identification of rapidly evolving categories

	Higher Ka/Ks				
Threshold	0.05	0.01	0.001	1.00E-04	1.00E-05

Supplementary Table S51 | Statistics regarding synteny. "SourceIndex" indicates the species in which syntenic gaps were found. "-", "I" and "D" represent gaps, lineage-specific insertions, and lineage-specific deletions, respectively. Yellow boxes highlight species lineage-specific insertions, while light blue boxes indicate deletions. Orange and blue boxes highlight family lineage-specific insertions and deletions, respectively.

Note: *P.tig* is the reference genome in the multiZ alignment.

b. Color index

Color Index:	Species specific	Family specific
Insertion	I	I
Deletion	D	D

Supplementary Table S52 | Statistics regarding lineage-specific insertions and deletions (indels). In accordance with the divergence time tree, we obtained the time to most recent common ancestor (TMRCA) for each selected species and tiger. We also obtained TMRCA of the Felidae family and dog. Then, the average mutation rate of indels was calculated for each species.

	Tiger	Cat	Dog	Human	Mouse	*Felidae*_specific
TMRCA (Myr)	10.00	10.00	58.00	103.00	103.00	58.00
Insertions/Myr	10.40	13.00	15.00	10.72	41.85	11.31
Deletions/Myr	12.20	29.00	15.50	18.95	66.34	12.62
InDels/Myr	22.60	42.00	30.50	29.67	108.19	23.93

Note: Syntenic segment is defined as continuous regions without any order or orientation change. Different cutoffs of syntenic segment, from 5Kb to 500Kb, were used to find inter-chromosomal and intra-chromosomal breakpoints. The dog genome was used as an outgroup.

Supplementary Table S55 | Integrated chromosomal rearrangement between tiger and domestic cat. The SyMAP and LASTZ approaches were integrated, and genomic positions, strand, and changed species were derived from results of the LASTZ approach.

Supplementary Methods

Genome sequencing and assembly

Sample preparation

The male Amur tiger (TaeGeuk), white tiger, African lion, and white African lion samples for genome sequencing were acquired from Everland Zoo of Korea (Supplementary Table S1). TaeGeuk, who has well-documented pedigree information, was confirmed as an Amur tiger by assessment of diagnostic subspecies specific synapomorphic mitochondrial DNA gene markers[1]. The snow leopard sample was acquired from the Conservation Genome Resource Bank for Korean Wildlife, Seoul National University, and the original sample (tissue) was imported from Mongolia with CITES permits (Mongolian export permit no. 0390, South Korean import permit no. ES2012-02507).

Amur tiger genome sequencing

Libraries of different insert sizes were constructed at BGI, Shenzen, China. The insert sizes of the libraries were 170bp, 500bp, 800bp, 2Kb, 5Kb, 10Kb, and 20Kb. Three short insert paired-end libraries (170bp, 500bp, and 800bp), and four long insert mate-pair libraries (2Kb, 5Kb, 10Kb, and 20Kb) were sequenced using HiSeq2000. A total of 288.20 billion base pairs were produced from 27 lanes. The average read length was 76.62bp (Supplementary Table S2). No chromosomal abnormalities were detected, and this lack of abnormality was confirmed by G-banded karyotype (Supplementary Fig. S1).

Raw read filtering for *de novo* assembly

In order to reduce sequencing error effects on the assembly, sequence reads were filtered for high quality[51] (Supplementary Table S3). Filtered, 242Gb sequences (around 100X average depth) were generated with an average read length of 77bp from 15 different (7 insert-size) libraries. The filtering criteria for exclusion were as follows:

1) Reads with ambiguous bases (represented by the letter N) for more than 5% of bases or poly-A structure contents.

2) Reads with 60% low-quality bases (base quality < 5) for the small insert-size libraries (170, 500 and 800bp) and reads with 30% low-quality bases for the large insert-size libraries.

3) Reads with adapter contamination: reads with more than 10bp aligned to the adapter sequence (no more than 3bp mismatch allowed).

4) Small insert-size reads in which read1 and read2 overlapped over 10bp or longer (10%

mismatch allowed).

5) PCR duplications (reads are considered duplications when read1 and read2 of the two paired end reads are identical).

6) Low-quality ends (obvious in terms of GC percentage composition) were trimmed directly.

Panthera species genome sequencing and filtering

Panthera species (white tiger, snow leopard, African lion, and white African lion) were sequenced at Theragen BiO Institute (TBI), Korea, using HiSeq2000 with read and insert lengths of 90bp and ~400bp, respectively.

For the comparative analysis, the sequence reads of the *Panthera* species were also filtered. Finally, on average 71.6 billion base pairs was produced, and the average genome coverage was ~30X (Supplementary Table S18). The filtering criteria for exclusion were as follows:

1) Reads with ambiguous bases (represented by the letter N) exceeds 10%.

2) Average quality of the read is under 15.

3) Nucleotides under quality 15 exceed 10% of a read.

4) For any read which contains an adapter sequence:

   A. More than 10bp of the tail of the first read and the head of the index adapter are identical.

   B. More than 10bp of the tail of the second read and the head of the universal adapter complementary sequence are identical.

5) Any read which contains PhiX or process control sequences.

De novo assembly of the Amur tiger genome

Prior to assembly, the sequencing errors were corrected based on K-mer frequency information[51]. For the Amur tiger genome assembly, we chose K=17bp and corrected sequencing errors for the 17-mers (expected frequency of 17-mers was 68) with a frequency lower than 18. In total, we corrected 0.21% of the bases and trimmed 3.97% of the bases from the filtered reads.

We estimated the Amur tiger genome size using K-mer analysis with K-mer size of 23bp. The genome size was calculated using the following formula: G=K_num/K_depth (K_num is the total number of K-mer, and K_depth is the frequency occurring more often than the others). The size of Amur tiger genome was estimated at 2.44Gb (Supplementary Fig. S2, Supplementary Table S4).

The Amur tiger genome was assembled using SOAPdenovo software[13], which employs the *de Brujin* graph algorithm. Only highly qualified data were used in the genome assembly. SOAPdenovo mainly consists of three key steps. Using this software, a total of 2.40Gb of scaffolds was assembled. The N50 of the scaffolds was 8.8Mb, and the size of the longest scaffold was 41.61Mb (Supplementary Table S5).

1) Contig construction: firstly, data from the short insert size library were used to construct a *de Bruijn* graph. Then, tips, merged bubbles, connections with low coverage, and small repeats were removed.

2) Scaffold construction: all qualified reads were realigned onto the contig sequences. We then calculated the amount of shared paired-end relationships between each pair of contigs, weighted the rate of consistent and conflicting paired-ends, and then constructed the scaffolds step-by-step, from short insert-size paired-ends, to long distance paired-ends.

3) Gap closure: The gaps between the constructed scaffolds were mainly composed of repeats that were masked off during scaffold construction. To close these gaps, the paired-end information was used to retrieve read pairs with one end mapped to a unique contig while the other was located in the gap region. Subsequently, a local assembly for these collected reads was performed.

The mapping depths of the assembled Amur tiger genome showed a normal distribution, indicating that there was no severe bias caused by repetitive sequences (Supplementary Figs. S3, S4). We used 10Kb non-overlapping sliding windows and calculated the GC content and average depth among these windows. To check whether the small block in the bottom of Supplementary Figure S3 originated from contamination from other species, some parts of the scaffolds were chosen from the small block and used as queries to perform BLAST[34] with the nt library. The scaffolds were most closely related to chromosome X of *Felis catus*, which indicates that the small block represents chromosome X of the Amur tiger.

Amur tiger draft chromosomes

Amur tiger draft chromosomes were constructed using the cat reference genome (Felis_catus-6.2). As the Amur tiger genome is very similar to the cat reference genome (Supplementary Table S11), the chromosomal location and ordering information of the tiger scaffolds could be derived from the cat genome (Supplementary Fig. S5). The methods used are detailed below.

1) Homozygous variations (719,258 of SNVs and 103,065 of indels), found by mapping the tiger short reads to the tiger scaffolds, were replaced with the nucleotides of the raw reads (Supplementary Tables S12, S13). We aligned the short reads of the Amur tiger to the scaffolds using BWA-0.5.9[52] with seed length 50 and edit distance 2, and variations were called from the depth of 5X ~ 300X using SAMtools-0.1.18[53].

2) The corrected tiger scaffolds were mapped to the cat genome, Felis_catus-6.2, using

SyMAP[49], and then the chromosomal location and order of the scaffolds were decided upon. Gaps between the located tiger scaffolds were estimated based on gaps in the alignment with the cat genome. When two tiger scaffolds overlapped, 20Kb was used as the size of the gap between the two scaffolds, because the longest insert size was 20Kb.

3) Additionally, we aligned tiger short reads to the cat genome using BWA with the same option described above, and continuous mapped regions (consensus sequences) with mapping depth over 1X were extracted (Supplementary Table S14). A total of 43,407,200 homozygous SNVs were used to generate the consensus sequences (Supplementary Table S15). The gap sequences between the tiger scaffolds were substituted with the consensus sequences if they were fully covered by the consensus sequences. As a result, 18 gaps (45,578 bp in length) in the tiger draft chromosomes were filled with the consensus sequences, which were generated by substituting the cat genome sequences with 956 tiger homozygous SNVs.

Finally, 571 of 674 scaffolds, 99.6% of total scaffold length, were placed in the Amur tiger chromosomes (Supplementary Tables S16, S17).

Assembly quality

In order to assess the assembly quality, the tiger blood transcriptome was sequenced using HiSeq2000 with read and insert lengths of 90bp and ~300bp, respectively. The transcriptome was assembled using Trinity[54]. The assembled transcripts were aligned to the assembly sequences using Blat with default parameters except an identity cutoff of 80%. As a result, >96% of the assembled transcripts were covered in the tiger scaffolds (Supplementary Tables S6, S7).

Published cat EST sequences were mapped to the tiger genome sequence (http://hgdownload.cse.ucsc.edu/goldenPath/felCat4/bigZips/est.fa.gz). The coverage rate was higher than 90%. Most of the unmapped EST segments were on the head or tail of the ESTs, and many of these segments were identified as having vector contamination (http://www.ncbi.nlm.nih.gov/VecScreen/UniVec.html). The mapping rate of the cat EST sequences was 98.9% (Supplementary Table S8).

Assembly quality was also assessed by mapping the tiger short reads to the tiger scaffold resulting in 95% of the reads mapped (Supplementary Table S12). A total of 719,258 homozygous SNVs and 1,262,207 heterozygous SNVs were found (Supplementary Table S13). A total of 78 heterozygous SNVs were validated by Sanger sequencing method, and 75 of them (96.2%) were true heterozygous SNVs (Supplementary Table S9).

Additionally, analysis of the tiger draft genome assembly for core eukaryotic genes[14] revealed homologs for >93.4% of conserved genes in the assembly (Supplementary Table S10).

Annotation of the assembled Amur tiger genome

Repeat annotation

We searched the genome for tandem repeats using the Tandem Repeats Finder[55] version 4.04. Transposable elements (TEs) were identified in the genome by homology-based approaches. The homology-based approach was used with Repbase[56] version 16.08, the commonly used database of known repeats. We used this database to find repeats using corresponding software such as RepeatMasker[57] version 3.3.0 and RMBlast[58] version 1.2. RepeatMasker was applied for DNA-level identification in combination with Repbase (Supplementary Fig. S13).

Gene prediction

Amur tiger genes were predicted as follows (Supplementary Tables S19, S20).

1) *De novo* prediction: *de novo* prediction was performed on the repeat masked genome based on HMM (hidden Markov model). Programs applied were AUGUSTUS[32] (version 2.5.5) and GENSCAN (version 1.0)[33].

2) Homology-based prediction: Homologous proteins of other species (from the Ensembl 60 release) were mapped to the genome using TblastN (Blast 2.2.23)[34] with an E-value cutoff of 1E-5. The aligned sequences, as well as its query protein, were then filtered and passed to GeneWise[35] (version 2.2.0) to search for accurate spliced alignments.

3) cDNA/EST-based prediction: Cat EST and full length cDNA sequences (from UCSC) were aligned to the genome using BLAT[36] (blat-34, identity ≥ 0.90, coverage ≥ 0.90) to generate spliced alignments. For EST results, spliced alignments were linked according to overlap using PASA[37].

4) Integration evidence: Source evidence generated from the three approaches mentioned above was integrated using GLEAN[38] to produce a consensus gene set.

5) Synteny detection: The Amur tiger genome sequence was aligned to two well assembled and annotated genomes (human and domestic cat) using LASTZ[59] (version 1.02). Then, mapped results yielding information on homologous proteins were filtered by syntenic blocks of genome sequences.

We also predicted the domestic cat (Felis_catus-6.2) gene set, because the gene set of the cat genome is preliminary. We used *de novo* and homology-based gene prediction methods, and the gene sets from two methods were merged to form a comprehensive and non-redundant reference gene set (Supplementary Tables S21, S22). We clustered the genes from all the input sets with a cut off of genomic overlap greater than 50 bp for each gene locus; we get larger CDS from human-derived, dog-derived and cow-derived. Finally, if no homologous

gene mapped, the *de novo* prediction was used. We had a much stricter cutoff for *de novo* genes than for homology genes. The one with the larger CDS from Genscan and Augustus was chosen and was required to have more than 30% aligning rate to the SwissProt/TrEMBL database[60,61] and had to have more than 3 exons.

Gene function annotation

Gene functions were assigned according to the best alignment match using Blastp with SwissProt and TrEMBL databases (Uniprot release 2011-01)[60,61]. The motifs and domains of genes were determined by InterProScan[62] (version 4.7) against protein databases, including ProDom[63], PRINTS[64,65], Pfam[66], SMART[67], PANTHER[68], and PROSITE[69]. Gene Ontology[70] IDs for each gene were obtained from the corresponding InterPro entries. All genes were aligned against KEGG[71] (Release 58) proteins, and the pathway in which the gene might be involved (Supplementary Table S23).

Detection of non-coding RNAs

We detected four types of non-coding RNA in the Amur tiger genome by searching databases using the whole genome sequence. tRNAscan-SE[72] (version 1.23) was performed on a SINE premasked genome in order to search for reliable tRNA positions. snRNA and miRNA were sought through a two-step method: after alignment with BLAST, INFERNAL was used to search for putative sequences in the Rfam database[73] (Release 9.1). Though *Panthera tigris* rRNA sequences were not available, we searched the genome using human full-length rRNA as queries for possible rRNA positions by BLAST with some restrictions (Supplementary Table S24).

Orthologous gene clusters

A comparative analysis was used to examine the rate of protein evolution and the conservation of gene repertoires among orthologs in the genomes of the Amur tiger, dog, human, mouse, giant panda, domestic cat (Felis_catus-6.2), and opossum. There were 17,841 orthologous groups and 8,875 single-copy gene families (Supplementary Fig. S6, Supplementary Table S25). We used the Treefam methodology[39] to define a gene family as a group of genes that descended from a single gene in the last common ancestor of a considered species.

BLASTP was used with all of the protein sequences against a database containing a protein dataset of all species under E-value 1E-7, and fragmental alignments were conjoined for each gene pair by Solar[74]. We assigned a connection (edge) between two nodes (genes) if more than 1/3 of the region was aligned to both genes. An H-score (minimum edge weight) that

ranged from 0 to 100 was used to weigh the similarity (edge). For two genes, G1 and G2, the H-score was defined as score (G1G2)/max (score(G1G1), score(G2G2)), where the score shown here is the BLAST raw score.

Gene families were extracted by clustering using Hcluster_sg[75]. We used the average distance for the hierarchical clustering algorithm, requiring the H-score to be larger than five, and the minimum edge density (total number of edges/theoretical number of edges) to be larger than 1/3. The clustering for a gene family would also stop if it already had one or more of the outgroup genes.

Genome evolution

Conserved sequences among genomes

We examined the Amur tiger's genomic elements that may have been evolutionarily conserved across species. PhastCons[76] was adopted to identify conserved elements with conservation scores, given a multiple alignment and a phylo-HMM. The parameter settings were "--target-coverage 0.3 --expected-length 45 --rho 0.31", and the phylogenetic model for non-conserved regions was produced by phyloFit in the PHAST package[77]. A total of 3.2% (77Mb) of the Amur tiger's genome sequence was conserved, which accounts for 0.19% of the genic region (Supplementary Table S49).

Lineage-specific insertions and deletions (indels)

For the synteny analysis, MULTIZ[78] was used to integrate all pairwise alignments together to identify conserved elements among the tiger, cat (Felis_catus-6.2), dog, human, and mouse genomes. For blocks longer than 500bp, species-specific and family-specific indels were counted according to the alignment data; indels located within 50bp of the end of the block, and pairs of indels less than 50bp apart were filtered out.

In accordance with the divergence time tree (see Supplementary Fig. S8), we obtained the time to most recent common ancestor (TMRCA) for each selected species and tiger. We also obtained TMRCA of the Felidae family and dog. Then, the average mutation rate of indels was calculated for each species (Supplementary Tables S51, S52).

Segmental duplication (SD)

Duplications were detected using whole-genome assembly comparison (WGAC). The self-alignment was generated by the LASTZ tool, with most parameters set as defaults. Before aligning, repeat sequences were masked, and the genome assembly was split into several

small sub-files. The maximum simultaneous gap allowed during aligning was 100bp. After aligning, we conducted self-to-self sequence alignment and identified 10,691 recent segmental duplicated fragments (>90% identity, >1Kb length) with a total length of 11.2Mb (0.47%) in the Amur tiger's whole genome assembly. Its recent segmental duplication rate was similar to that of giant panda (10.4Mb, 0.43%)[51] and lower than that of dog (43.8Mb, 1.73%)[79] as detected using the same whole-genome assembly comparison method (Supplementary Table S50). This low segmental duplication rate may be due to an over-collapsing of duplications, a common error seen in assemblies from next generation sequencing technologies[80].

Chromosomal rearrangement

Among the alignment data generated from SyMAP[49], when one scaffold happened to be mapped to several physically distant cat (Felis_catus-6.2) chromosomal locations, they were considered to be inter- or intra-chromosomal rearrangement events of the Amur tiger genome relative to the cat genome (Supplementary Table S53). A total of 30 breaks, i.e., large-size inter- or intra-chromosomal rearrangements, were detected using SyMAP. The species (tiger and domestic cat)-specific genomic rearrangements were also analyzed. We performed the dog vs. tiger and cat vs. tiger whole-genome pair-wise alignments using LASTZ software on the repeat-masked genomes. Using these methods, we identified clusters of unique alignments with well-defined order and orientation. These clusters were defined as syntenic segments. Different cutoffs (5Kb to 500Kb) were tested for the minimum syntenic segment size and various counts of intra-chromosomal and inter-chromosomal breakpoints were calculated (Supplementary Table S54).

There was a total of 18 chromosomal rearrangement (12 inter- and 6 intra-chromosomal rearrangements) overlaps (Supplementary Table S55) when the results from SyMAP and LASTZ were integrated by comparing syntenic break positions. As the tiger assembly was generally fragmented, we carefully validated the 18 syntenic breaks to examine the assembly integrity by aligning long insert mate-pair libraries (2Kb, 5Kb, 10Kb, and 20Kb) to the tiger scaffolds. Finally, we reported six putative chromosomal rearrangements (two inter- and four intra-chromosomal rearrangements) between the tiger and cat. All six rearrangements were validated by long range PCR experiments followed by the Sanger sequencing method (Supplementary Fig. S14, Supplementary Table S56).

Gene evolution

Phylogenetic analysis of Amur tiger and other mammals

A phylogenetic tree of the Amur tiger and the other sequenced genomes was constructed using single-copy gene families. For each species, 4-fold degenerate sites were extracted

from each family and concatenated to one super gene. A substitution model (HKY85+gamma+I) was selected, and PhyML[81] was used to construct the phylogenetic tree (Supplementary Fig. S7).

Estimation of divergence time and substitution rate

We estimated the divergence time for the seven mammalian species (tiger, human, dog, mouse, giant panda, opossum, and domestic cat (Felis_catus-6.2)) using single copy gene families and 4-fold degenerate sites (neutral substitution rate per year). PhyML molecular dating was adopted to estimate the neutral evolutionary rate and species divergence time using the program MCMCTREE[82], which is implemented in the PAML package[83]. The divergence time of tiger and cat was estimated to be 10 (8-15) MYA, and the substitution rate of tiger (1.6E-09) was similar to that of human (1.4E-09) (Supplementary Fig. S8).

Phylogenetic analysis of Amur tiger and other Felidae

We also estimated the divergence time among Felidae specifically, using dog genome as an outgroup. All filtered reads were mapped to the cat reference genome sequence, CAT.66 build from Ensembl (Supplementary Table S58). Mapping was conducted using the BWA program with default options.

Single nucleotide variations (SNVs) were scanned from SAMtools pileup files. Variations were detected from the depth of 5-150X (Supplementary Table S59). Reads of the Amur tiger were filtered using the same criteria used for the other big cat genomes. Then, variations were scanned.

By using 2,888 orthologous genes between the domestic cat and dog from OrthoDB[84] and mapping the big cat reads to the domestic cat, 1,904 efficiently covered genes (depth: 5-60X, ≥50% of CDS coverage) were found. SNVs detected in this way were used to select big cat gene sequences by substituting the variations, and the sequences were multiply-aligned for all of the genes. Gapped regions of the multiply aligned genes were removed, and, finally, 270,540bp on the 4-fold degenerate sites were collected and used to construct the phylogenetic tree (Supplementary Fig. S15). We adopted <16.0 and >1.0 million years as fossil record constraints of divergence time for domestic cat vs. big cats and snow leopard vs. tiger, respectively. The estimated divergence time was similar to that predicted by fossil records and close to the 10.8MYA date developed by a recent comprehensive Felidae phylogeney. Tiger, lion, and snow leopard diverged at about 2-4 MYA (Supplementary Fig. S16), and the snow leopard was closer to the tiger than to the lion, affirming earlier inferences[15,16]. The phylogenetic tree construction was extremely consistent under bootstrapping analysis (100% for all of the branching points).

Gene expansion and contraction

Among 14,425 orthologous gene families, 103 shared orthologous gene families were specific to the tiger and the cat. The Felidae-specific gene families contained 129 genes and 287 InterPro domains, and gene list of the Felidae-specific gene families and tiger/cat-specific gene families are shown in Supplementary Tables S26, S27, respectively (sequence data is available at http://tigergenome.org). The Felidae- and Amur tiger-specific protein domains are shown in Supplementary Tables S28, S29.

Lineage-specific gene family expansion and contraction may be associated with specific functions, phenotypes, and physiology. We determined the expansion and contraction of the orthologous protein families among seven mammalian species (tiger, cat (Felis_catus-6.2), dog, human, mouse, giant panda, and opossum) using CAFÉ 2.2[40] with 0.001080 of lambda option. GO of all tiger genes was annotated by InterPro. ChiSquare test followed by Fisher's exact test (p-value≤0.01) was used to test for over-represented functional categories among expanded genes and 'genome background' genes; Fisher's exact test was used when any expected value of count was below 5, which would have made the ChiSquare test inaccurate[41]. Compared to the feline common ancestor, the tiger genome is enriched in olfactory receptor activity, G-protein coupled receptor signaling pathway, signal transducer activity, amino acid transport, and protein metabolic process (Supplementary Table S30). All olfactory receptor gene families, which were expanded in the tiger compared to the feline common ancestor, are shown in Supplementary Fig. S9.

Positively selected genes (PSG)

Genome-wide scan for positively selected genes (PSGs) in mammals can provide insight into the dynamics of genome evolution, the genetic basis for differences among species, and the functions of individual genes[85]. We used conserved genome synteny methodology[19] to establish a high-confidence orthologous gene set. Briefly, whole-genome multiple alignments were performed between human (hg19) and other species (cat (Felis_catus-6.2), dog (CanFam2.0), mouse (mm9), and panda (ailMel1) genomes) by the Lastz alignment pipeline. We collected all the human protein-coding genes from RefSeq[43], KnownGene[44], and VEGA[45], and mapped them to the other species via the syntenic regions. We then filtered the resulting blocks with rigorous conditions to get large-scale synteny of high alignment quality, and a conservation of exon-intron structure. Finally, we found 7,415 1:1 high quality ortholog genes to analyze (Supplementary Table S35), most of which also correspond to genes in the panda, dog, and mouse genomes.

To detect tiger genes evolving under positive selection, we aligned ortholog genes by PRANK[46] and used the optimized branch-site model of PAML (version 4.5) and likelihood ratio tests (LRTs) (P-value ≤ 0.05). A total of 178 PSGs were identified (Supplementary Data 1). A GO annotation download from Ensembl was used to assign GO categories to 7,415 orthologs. ChiSquare test followed by Fisher's exact test (P-value ≤ 0.01) was used to test for over-represented functional categories among PSGs (Supplementary Data 2); Fisher's exact test was used when any expected value of count was below 5, which would have made the

ChiSquare test inaccurate[41]. KEGG pathway analysis results for the Amur tiger's PSGs are shown in Supplementary Table S36.

Rapid evolution

We used an approach based on *Ka*/*Ks*[47,48] to identify GO categories that significantly above or below average in the tiger genome. Firstly, the *Ka* and *Ks* rates are estimated by PAML from all aligned bases with quality score > 20 in orthologs, using the F3x4 codon frequency model and the REV substitution matrix. To explore the evolution function catalog, we download the Gene Ontology (GO) annotation of human gene from the Ensembl database (release-69). We calculated the average Ka and Ks values for all genes that have annotated GO as following equations (S1, S2).

$$k_a = \frac{\sum_{ieT} a_i}{\sum_{ieT} A_i} \qquad \text{(S1)}$$

$$k_s = \frac{\sum_{ieT} s_i}{\sum_{ieT} S_i} \qquad \text{(S2)}$$

Where T is the number of annotated GO genes, a_i and A_i are the numbers of non-synonymous substitutions and sites, and s_i and S_i are the numbers of synonymous substitutions and sites in gene *i*, as estimated by PAML, respectively.

The expected proportion of non-synonymous substitutions p_A in a GO category was then estimated (S3).

$$p_A = \frac{k_a \sum_{ieC} A_i}{k_a \sum_{ieC} A_i + k_s \sum_{ieC} S_i} \qquad \text{(S3)}$$

For a given GO category C, the probability p_c of observing an equal or higher number of non-synonymous substitutions was calculated assuming a binominal distribution (S4).

$$p_c = \sum_{j-a_c}^{a_c+s_c} \binom{a_c+s_c}{j} p_A^j (1-p_A)^{a_c+s_c-j} \qquad \text{(S4)}$$

where a_C and s_C are the total number of non-synonymous and synonymous substitutions in GO category *C*, respectively.

To determine whether the GO categories are evolving under significantly high constraints, we repeated this procedure 10,000 times on the same dataset after randomly permuting the GO annotations to test whether p_C is less than a threshold value. Then, we acquired the GO

categories if the p-value was less than 0.05 (Supplementary Tables S37, S38). Finally, 41 and 22 GO categories were selected to be rapidly and slowly evolving, respectively (Supplementary Tables S40, S41).

We also used a similar approach to the binomial test described above to identify GO categories that have an excess of non-synonymous changes on one lineage. Lineage-specific rates were estimated using a rooted tree including human, tiger, and cat.

For lineages x and y, the average proportion of non-synonymous substitutions were calculated by the following formula (S5).

$$p_x = \frac{x}{x+y} \text{ , which } x = \sum_i x_i \text{ , } y = \sum_i y_i \qquad \text{(S5)}$$

Where $x = \sum_i x_i$, $y = \sum_i y_i$, x is the total number of non-synonymous substitutions in the x lineage, y is the total number of non-synonymous substitutions in the y lineage, and the divergence of the proportion of non-synonymous substitution numbers in different lineages between the observed and expected obeys binomial distribution, the formula is as in the following equation (S6).

$$p_c = \sum_{j-x_c}^{x_c+y_c} \binom{x_c+y_c}{j} p_x^j (1-p_x)^{x_c+y_c-j} \qquad \text{(S6)}$$

As described for the absolute rate tests, we then computed this statistic for every GO category with more than 20 orthologs, as well as for every category in 10,000 randomly permuted data sets (Supplementary Table S39). The tiger- and cat (Felis_catus-6.2)-specific GOs under rapid evolution are shown in Supplementary Tables S42, S43, respectively.

Unique amino acid changes

We investigated *Panthera* lineage-specific amino acid changes by comparison with the known genes from the human, dog, and mouse (from the Ensembl 69 release). We used lion and snow leopard gene sets by mapping reads to the tiger scaffolds and substituting SNVs (Supplementary Tables S31, S32). Artifacts from the multiple sequence alignments (ClustalW2[42]) limitation were removed by filtering option with ≥1/2 of coverage and ≥ of well-matched amino acids (consensus string is '*', ':', or '.'). A total of 3,646 genes had the big cat-specific amino acid changes, and 5,882 genes had unique amino acid changes that are shared in the feline lineage (big cats and domestic cat (Felist_catus-6.2)). Pathway analysis for the genes having functional changes (PolyPhen2[17]) in big cat and feline lineage are shown in Supplementary Tables S33, S34, respectively.

The protein sequences of *EGLN1*, *EPAS1*, and *TYR* were produced by mapping big cat raw

reads to the Amur tiger genome. After variant calling using SAMtools (the depth of 5-150X), both homozygous and heterozygous substitutions were selected for the multiple sequence alignment. The snow leopard-specific amino acid change in *EGLN1* (Met39) was located adjacent to the catalytic channel (Supplementary Fig. S10). We also found snow leopard-specific amino acid changes in the *EPAS1* gene such as Ile663 and Arg794 (Supplementary Fig. S11). Arg794 was found to be possibly damaging causing protein functional changes by computational prediction.

Four nucleotide variants causing amino acid changes in snow leopard (*EGLN1* and *EPAS1*) and white lion (*TYR*) were validated by Sanger sequencing, and they were the snow leopard- and white lion-specific variations, respectively (Supplementary Table S44). Two snow leopard-specific amino acid changes in the *EPAS1* gene were heterozygous variations.

Population genetic analysis of white lion and snow leopard

To verify the proposed candidate mutation in *TYR* gene, a total of 52 samples were included in this study (Supplementary Fig. S12, Supplementary Tables S46, S47), and one DNA sample was made available without extraction history; the following protocols were used for the remaining samples. DNA was extracted from 3 blood and 18 hair samples with the DNeasy Blood & Tissue Kit (Qiagen), following the manufacturer's protocol and a published user-developed protocol, respectively. DNA was extracted from 3 FTA blood samples following protocol 4 in a previously published paper[86]. DNA was obtained from 3 tissue and 24 blood samples (22 EDTA blood samples, 2 heparin blood samples); tissue samples were cut up finely, and red blood cells in blood samples lysed prior to enzymatic digestion (Proteinase K) and phenol:chloroform:isoamyl alcohol extraction[87] with a modified lysis buffer. DNA dilutions were determined based on quantification with a NanoDrop® ND-1000 Spectrophotometer (ThermoScientific) or amplification success. Five samples (2 blood and 3 hair samples) were dropped because of lack of amplification or insufficient sequence quality.

PCR and sequencing: Primers (Supplementary Table S48) to amplify the first part of *TYR* exon 1, including the candidate mutation, were designed with Primer3 (http://frodo.wi.mit.edu/cgi-bin/primer3/primer3_www.cgi)[88] based on the domestic cat genome sequence assembly[8].

Amplification and sequencing was performed following three different protocols.

Veterinary Genetics Laboratory: A 20µl reaction was set up containing 0.2µM forward and reverse primers, 0.0125U Super-Therm Gold DNA Polymerase with 1x Buffer and 1.5mM $MgCl_2$ (Separation Scientific), 250µM dNTPs (Life Technologies), and 0.5µl DNA (5 to 50 ng/µl). PCR was performed on a GeneAmp ® PCR system 9700: 95°C for 5 min; 35 cycles of 95°C for 1 min, 58°C for 30 sec, and 72°C for 30 sec, and a final extension of 72°C for 30 min. The PCR product was cleaned up with MSB® Spin PCRapace (Invitek) following

Protocol 1 with a final elution volume of 20µl. A 10µl sequencing reaction was set up containing a 2µl ABI Prism® BigDye® Terminator v3.1 mix and 1µl buffer (Applied Biosystems), a 0.32µM forward or reverse primer, and a 6µl PCR product. The sequencing reaction was performed on a GeneAmp ® PCR system 9700 according to the Perkin Elmer temperature and time requirements. Sequencing products were purified with an ethanol precipitation and analyzed on a 3130xl Genetic Analyzer (Applied Biosystems).

Institute of Environmental Sciences: A 20µl reaction was set up containing 0.4µM forward and reverse primers, 200µM dNTPs (BioLine), a 0.1U/µl Taq Polymerase with 1x PCR buffer and 1mM $MgCl_2$ (Qiagen), 0.4mg/ml bovine serum albumin (Promega), and 2µl DNA (2-20 ng/µl). PCR was performed on a Bio-Rad S1000 Thermal Cycler PCR system 9700: 94°C for 4 min; 40 cycles of 94°C for 20 sec, 54.5 or 56.6°C for 1 min, and 72°C for 1 min; and a final extension of 72°C for 10 min. PCR products were sent to Macrogen (Amsterdam, The Netherlands) for sequencing.

LifeTechnologies Conservation Genetics Laboratory: A 15µl reaction was set up containing 0.4µM forward and reverse primers, a 0.05U/µl MyTaq HS DNA Polymerase with 1x Buffer and 3mM $MgCl_2$ and 250µM dNTPs (Bioline), and 1.5µl DNA. A touch down PCR was performed on a GeneAmp ® PCR system 9700: 94°C for 10 min; 10 cycles of 94°C for 15 sec, 60-51°C (decreasing 1°C at each cycle) for 30 sec, and 72°C for 45 sec; 30 cycles of 94°C for 15 sec, 50°C for 30 sec, and 72°C for 45 sec; and a final extension of 72°C for 30 min. PCR products were assessed with an agarose electrophoresis and purified with illustra ExoStar (GE Healthcare Life Sciences). If deemed necessary, a second semi-nested PCR reaction was performed with a nested Forward primer following the same amplification and purification protocols as the first PCR. A 10µl sequencing reaction was set up containing a 2µl ABI Prism® BigDye® Terminator v3.1 mix and 1µl buffer (Applied Biosystems), a 0.2µM reverse primer, and a 1-1.5µl PCR product. The sequencing reaction was performed on a GeneAmp ® PCR system 9700 according to the Perkin Elmer temperature and time requirements. Sequencing products were purified with an ethanol precipitation and analyzed on a 310 Genetic Analyzer (Applied Biosystems).

***Analysis*:** All data files were analyzed in Geneious v.6.0.3 (Biomatters; http://www.biomatters.com). Two sequence variants were evaluated. The degree of concordance between expected and observed genotypes were calculated, to test whether the molecular variant that differed from the other felid sequences could be responsible for the white phenotype in lion.

To verify the observed mutation in the *EGLN1* gene, samples from an additional 42 individuals from 5 species (snow leopard, tiger, lion, leopard, and clouded leopard) were sequenced (Supplementary Table S45). Primer information for the *EGLN1* gene is listed in Supplementary Table S44. A 15µl reaction was set up containing 0.4µM forward and reverse primers, 0.05U/µl AmpliTaq DNA Polymerase with 10x Buffer and 3mM MgCl2 and 250µM dNTPs, and approximately 20ng DNA. A touch down PCR was performed on a GeneAmp® PCR system 9700: 94°C for 10 min; 10 cycles of 94°C for 15 sec, 60-51°C (decreasing 1°C at each cycle) for 30 sec, and 72°C for 45 sec; 30 cycles of 94°C for 15 sec, 50°C for 30 sec,

and 72°C for 45 sec; and a final extension of 72°C for 30 min. PCR products were assessed with an agarose. Cycle sequencing reactions consisted of a 0.25U BigDye® Terminator v3.1 Ready Reaction Mix, a 0.075μM primer, 5μL of sequencing buffer (Applied Biosystems), 1.5μL of purified PCR product, and enough water for a 10μL reaction. Cycle sequencing was performed under the following conditions: 94°C for 10 sec, 52°C for 5 sec, and 72°C for 2 min for 45 cycles. Products from cycle sequencing reactions were run on an ABI 3730 DNA Analyzer. Sequence results were visualized and edited in Geneious® (Biomatters; http://www.biomatters.com). All snow leopards had the same amino acid change in *EGLN*1 (Met39), which was not observed in any of the other felid species tested.

Genetic Diversity

Heterozygous SNVs of two tiger genomes, two lion genomes, and one snow leopard genome were calculated by mapping raw reads to the Amur tiger genome (Supplementary Table S32). All genome sizes were assumed to be the same as that of the Amur tiger. Heterozygous SNVs of a recently sequenced human genome (Korean female, from the Korea Personal Genome Project[89], using the same sequencing machine and methods as those used for the present study) were calculated by mapping raw reads to the human reference genome (hg.19). The number of heterozygous SNVs, as well as the genome sizes of the eight species used for comparison, were cited individually from their initial genome sequence reports[8,22,28,30,48,51,90]. Overall, the span of tigers' genetic diversity was similar to that of human, but higher than those of lion and snow leopard. Among the tiger subspecies, the genetic diversity of TaeGeuk (Amur tiger) was relatively lower than that of white tiger (Supplementary Table S57).

Demographic history

The history of population size helps to develop insights into evolution. Based on the pairwise sequentially Markovian coalescent model (PSMC)[31], we inferred detailed population size histories of Amur tiger (TG), African lion (LN), snow leopard (SL), white tiger (WTG), and white lion (WLN).

Using SNV datasets scanned with the all the big cat sequencing reads mapped to Felis_catus-6.2 (BWA-0.5.9 and SAMtools-0.1.18), the consensus sequences of each big cat were constructed and then divided into non-overlapping 100-bp bins marked as homozygous or heterozygous. The resultant bin sequences for their sex chromosomal parts were removed and then they were taken as the input of the PSMC estimation. To test the estimation accuracy, bootstrapping was performed by randomly resampling 100 sequences from the original sequences. Using the neutral mutation rates calculated previously (Supplementary Information section 4.3), the raw PSMC outputs were scaled to time and population sizes (Supplementary Fig. S17). To study the detailed distribution of time to the most recent

common ancestor (TMRCA) and its relationship with evolution, parameters of each bin were decoded with the software and scaled to time (Supplementary Fig. S18). Climate change and migration are two important factors influencing the population size. Thus, we obtained atmospheric surface air temperature (Tsuf) and global relative sea level (RSL) data of the past 3 million years[50] from National Climatic Data Center (NCDC) and combined them together with the 5 big cat demographic data into a single plot).

Since the neutral mutation rate varies with chromosome regions and mutation types, the time and size scaling of our inference could be affected by inaccurate estimation of neutral mutation rates. The inferred history of snow leopard shows a distinct shape, especially in early (0.5 Myr) and recent (3 Kyr) stages. This could be an artifact probably due to the model limitations occurring when there is extremely low genetic diversity.
