

Supplementary Method: Opal and particulate scavenging controls on Atlantic $^{231}\text{Pa}/^{230}\text{Th}$ time-series

In order to examine a potential scavenging control on past $^{231}\text{Pa}/^{230}\text{Th}$ changes by opal and particulate fluxes in the Atlantic Ocean for the last 25 thousand years (kyr), we have carried out individual correlation analysis on each of the thirty-three available sedimentary $^{231}\text{Pa}/^{230}\text{Th}$ time-series for this region (Supplementary Fig. 1 & 2) with the corresponding ^{230}Th -normalised (vertical) opal flux and bulk sediment flux.

Strong positive correlations between $^{231}\text{Pa}/^{230}\text{Th}$ and opal flux with r values of 0.60 to 0.98 are observed in fourteen cores, which include two cores from the South-East Atlantic^{1,2}, six cores from the equatorial Atlantic³, one core from the Brazil margin⁴, two cores from southern Ceara Rise², one core from the Blake Ridge², and two cores from the Rockall Basin⁵ (Supplementary Fig. 3). The two Rockall Basin cores that show r values of 0.63 and 0.69 for opal flux– $^{231}\text{Pa}/^{230}\text{Th}$ correlation display persistent $^{231}\text{Pa}/^{230}\text{Th}$ values well above the production ratio (>0.093) during early deglacial⁵. Although other processes have been suggested⁵ to contribute to the high $^{231}\text{Pa}/^{230}\text{Th}$ observed, opal flux is generally higher during this period of preferential scavenging of the ^{231}Pa isotope⁵, suggesting a scavenging control by opal in these two cores. This observation supports our approach of considering the influence of opal scavenging on past $^{231}\text{Pa}/^{230}\text{Th}$ changes for cores which show $r>0.6$ for the opal flux– $^{231}\text{Pa}/^{230}\text{Th}$ correlation.

Among the strong positive opal flux– $^{231}\text{Pa}/^{230}\text{Th}$ correlations ($r>0.6$) observed in the fourteen cores, three have p -values of greater than 0.05 (Supplementary Fig. 3), suggesting the possibility of the statistical correlation being caused by random chance for these three cores (two southern Ceara Rise cores and one core from the South-East Atlantic). It should also be noted that post-depositional opal dissolution is a source of uncertainty in ^{230}Th -normalised opal flux, which has implications for the correlation between $^{231}\text{Pa}/^{230}\text{Th}$ and opal flux³. This uncertainty remains unconstrained, and might become more important when there is temporal change in opal preservation³ that could be driven by processes such as changes in Atlantic water mass composition, given that Atlantic water masses have different dissolved silicon content. Despite the uncertainties above, we decide to take a conservative approach to minimise the potential overprint of opal scavenging. Based on the Rockall Basin observations explained above, the fourteen cores that show $r>0.6$ for the opal flux– $^{231}\text{Pa}/^{230}\text{Th}$ correlation, including the three cores that show $p>0.05$, are excluded from further interpretation of Atlantic circulation changes.

Thirteen cores from the West and deep (>2.5 km) East Atlantic, which include nine previously published cores^{2,3,6-10} and four new cores, exhibit lower correlations ($r<0.6$) between $^{231}\text{Pa}/^{230}\text{Th}$ and opal flux/diatom flux/diatom abundance (Supplementary Fig. 4). In addition, none of these cores show strong positive correlation ($r<0.6$) between $^{231}\text{Pa}/^{230}\text{Th}$ and bulk sediment flux. Together, the correlation analyses suggest that opal and bulk sediment scavenging are not the main controls of past $^{231}\text{Pa}/^{230}\text{Th}$ changes observed in these thirteen cores.

70 There is no evidence of a strong positive correlation between $^{231}\text{Pa}/^{230}\text{Th}$ and both opal and bulk
71 sediment fluxes ($r < 0.04$) in any of the six East Atlantic records from the intermediate depths (1–2.5
72 km)^{5,9,11–13} (Supplementary Fig. 5). This result indicates that opal and bulk sediment fluxes is likely
73 not the most important influence on past $^{231}\text{Pa}/^{230}\text{Th}$ changes in these intermediate-depth East
74 Atlantic cores.

75
76 Some of the adjacent cores show substantial differences in the correlation between $^{231}\text{Pa}/^{230}\text{Th}$
77 and opal/diatom flux, such as those from off Namibia (25° S, 3.51 km, $r = 0.66$ and 23° S, 1.97 km,
78 $r = -0.38$), Brazil margin (2° S, 1.37 km, $r = 0.71$ and 2° S, 2.25 km, $r = 0.33$), and the Rockall basin (53°
79 N, 4.05 km, $r = 0.63$ and 50° N, 4.28 km, $r = -0.17$) (Supplementary Fig. 1–5). These cores are situated
80 at or proximal to the continental margins and oceanic plateau, and marine primary production
81 (including opal) could have significant local variations at these settings¹⁴. Given that opal
82 effectively scavenges ^{231}Pa and can significantly reduce the residence time of ^{231}Pa in seawater¹⁵,
83 $^{231}\text{Pa}/^{230}\text{Th}$ could be modified by opal scavenging at a relatively local scale, which might give rise to
84 the observed differences in the correlation of $^{231}\text{Pa}/^{230}\text{Th}$ with opal at adjacent sites at margins
85 and over submarine plateau.

Supplementary Figure 1. Site map of all sedimentary $^{231}\text{Pa}/^{230}\text{Th}$ records examined in this study. Star symbols represent cores that are influenced by opal scavenging (Supplementary Fig. 3), and the other symbols indicate cores that are not dominantly influenced by opal scavenging (Supplementary Fig. 4 & 5): squares are new $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study, empty circles are intermediate-depth East Atlantic cores, filled circles are West and deep East Atlantic cores. The bracketed numbers denote the identity of the sediment records plotted in the subsequent supplementary figures, with references listed in Supplementary Table 1. Core [1]–[13] are records selected for the interpretation of deep Atlantic circulation (main text Fig. 1). The map was generated using the Ocean Data View program (Schlitzer, R., Ocean Data View, <http://odv.awi.de>, 2016).

Supplementary Figure 4. Sedimentary $^{231}\text{Pa}/^{230}\text{Th}$ versus ^{230}Th -normalised (a) opal flux, (b) diatom flux, diatom abundance, and (c) bulk sediment flux for West and deep (>2.5 km) East Atlantic records that show $r < 0.6$ for correlations between opal flux/diatom flux/diatom abundance and $^{231}\text{Pa}/^{230}\text{Th}$. Error bars represent 2 s.e.m. The correlations incorporate data solely from 0–25 ka core intervals. Diatom fluxes (diatom is the main component of opal) for the Bermuda Rise (34° N, 4.58 km) and Iberian margin (38° N, 3.14 km) cores were not calculated because the diatom abundance data of the Bermuda Rise core is semi-quantitative and the diatom abundance data for the Iberian margin core is from a nearby core¹⁶. Bracketed numbers denote the core identities marked in Supplementary Fig. 1, with references listed in Supplementary Table 1. Bold characters in the figure legend and the square symbols indicate $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study.

Supplementary Figure 5. Sedimentary $^{231}\text{Pa}/^{230}\text{Th}$ versus ^{230}Th -normalised **(a)** opal flux, diatom flux, and **(b)** bulk sediment flux for intermediate depth (1–2.5 km) East Atlantic records. Error bars represent 2 s.e.m. The correlations incorporate data solely from 0–25 ka core intervals. Bracketed numbers denote the core identities marked in Supplementary Fig. 1, with references listed in Supplementary Table 1.

Supplementary Figure 6. Time-series of (a) North Atlantic ice-rafted debris (IRD) records¹⁷⁻¹⁹ and a proxy record (BIT index) of Eurasian fluvial discharge²⁰, (b) composite $^{231}\text{Pa}/^{230}\text{Th}$ record, and (c) Northern Greenland ice core temperature proxy ($\delta^{18}\text{O}$) record²¹ from 21 to 10 ka. The composite $^{231}\text{Pa}/^{230}\text{Th}$ record was developed to represent the coherent trends observed in the western and deep high latitudinal cores at the North Atlantic (main text Fig. 2), and to highlight the timing of inferred variations in AMOC strength. The composite does not show the range of $^{231}\text{Pa}/^{230}\text{Th}$ given the range of water depths, latitudes, and oceanic environment the cores sit at, although this range does not undermine the millennial-scale signal associated with the variations in AMOC strength. The composite was derived by computing 9-point moving averages, which integrates data over 500–1,000 years. The choice of data integration is a suitable compromise for accounting sediment chronology uncertainty and preserving changes on the millennial timescale. Given the reason above, the composite is not expected to capture abrupt changes on the decadal or shorter timescale. Two other western cores (42° N, 4.11 km; 34° N, 4.58 km) do not have data over the Holocene and late deglacial (<13 ka) (main text Fig. 2), and so are excluded from the composite. An alternative composite curve was developed using the data binning method (Supplementary Fig. 7). Triangle and diamond symbols respectively signify ^{14}C and non- ^{14}C chronological tie-points. Numbers and letters in brackets denote the identity of the sediment cores marked in main text Fig. 1, with references listed in main text Table 1. Bold characters in the figure legend and the square symbols indicate new $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study. Yellow shading – early HS1, blue shading – late HS1, green shading – YD, grey shading mark the HS1-BA transition and the YD-early Holocene transition.

145
 146 **Supplementary Figure 7.** Alternative composite $^{231}\text{Pa}/^{230}\text{Th}$ curve developed using the data binning method. The
 147 $^{231}\text{Pa}/^{230}\text{Th}$ data was binned at equally spaced 500-year intervals from 20–10 ka (data binned at 1,000-year
 148 interval for 21–20 ka due to lower data resolution). The 1 standard deviation of the binned dataset represents
 149 the range of $^{231}\text{Pa}/^{230}\text{Th}$ data given the range of water depths, latitudes, and oceanic environment the cores sit
 150 at. The composite curve developed using the data binning method is very similar to the one developed using the
 151 moving average method (Supplementary Fig. 6). Triangle and diamond symbols indicate respectively the ^{14}C and
 152 non- ^{14}C chronological tie-points of the sediment core age models. Bracketed numbers denote the core identities
 153 marked in Supplementary Fig. 1, with references listed in Supplementary Table 1. Bold characters in the figure
 154 legend and the square symbols indicate $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study. Error bars represent 2 s.e.m.
 155 of the individual $^{231}\text{Pa}/^{230}\text{Th}$ data points. Yellow shading – early HS1, blue shading – late HS1, green shading – YD.

Supplementary Figure 8. Site maps of JC094-GYV14, JC094-GYV01, EW9209-1JPC and EW9209-3JPC sediment cores. The maps were generated using the Ocean Data View program (Schlitzer, R., Ocean Data View, <http://odv.awi.de>, 2016).

160
 161 **Supplementary Figure 9.** Planktonic $\delta^{18}\text{O}$ records of GYV14 and GYV01. The measurements were carried out on
 162 10–12 specimens of the planktonic foraminifera, *G. ruber*, picked from the 250–355 μm size fraction, and
 163 analysed using a Thermo Delta V Plus mass spectrometer coupled with a Kiel IV automated carbonate-sample
 164 preparation device, in the New Core Lab stable isotope laboratory at the Lamont-Doherty Earth Observatory.
 165 Calibration of measurements to the Vienna Peedee belemnite (VPDB) isotope scale was carried out using NBS-19
 166 and NBS-18 reference materials²². The in-house standard 1 s.d. reproducibility for $\delta^{18}\text{O}$ is ± 0.06 ‰.

NOSAMS – National Ocean Sciences Accelerator Mass Spectrometry Facility measurements

NRCF – East Kilbride NERC Radiocarbon Facility measurements

Supplementary Figure 10. Sediment age-depth models for the four new $^{231}\text{Pa}/^{230}\text{Th}$ records – (a) GVV14, (b) GVV01, (c) 1JPC, and (d) 3JPC developed using the OxCal Poisson deposition model²³ based on chronological tie-points derived from ^{14}C measurements and benthic foraminiferal $\delta^{18}\text{O}$ record²⁴. The ^{14}C ages were obtained by dating planktonic foraminifera *G. sacculifer* picked from the $>250\ \mu\text{m}$ size fraction. Blue shading represents 2 s.d. uncertainties associated with the age models. For 1JPC, samples for the published ^{14}C ages²⁵ were acquired from the working half of core and were in stratigraphic order. In contrast, age inversions were observed in the new ^{14}C dates acquired from recent sampling in 2013 at 32–38 cm sediment depths of the archive half of core. The $^{231}\text{Pa}/^{230}\text{Th}$ data acquired from those potentially disturbed samples (32–38 cm sediment depths of archive half) (Supplementary Fig. 12) are not included in the final result figures.

Supplementary Figure 12. (a) Sedimentary $^{231}\text{Pa}/^{230}\text{Th}$, **(b)** ^{230}Th -normalised bulk sediment flux and **(c)** opal flux reconstructions for GVV14, GVV01, 1JPC and 3JPC. Error bars represent 2 s.e.m. Triangle and diamond symbols indicate respectively the ^{14}C and non- ^{14}C chronological tie-points of the sediment core age models. The sedimentary $^{231}\text{Pa}/^{230}\text{Th}$ data calculated by assuming a lithogenic $^{238}\text{U}/^{232}\text{Th}$ activity ratio of 0.6 (square symbols with solid lines) and 0.5 (circle symbols with dashed lines) respectively are within analytical uncertainty. Grey symbols mark the previously published 3JPC data²⁶ that were re-calculated here using the new sediment age model (Supplementary Fig. 10). Filled squares/circles indicate $^{231}\text{Pa}/^{230}\text{Th}$ measurements made at the Woods Hole Oceanographic Institution and at the Lamont-Doherty Earth Observatory, while empty squares/circles indicate those made at the University of Bristol. Measurements of 1JPC 32.5 cm (15.0 ka) and 36 cm (16.6 ka) sediment core depths were excluded from the final result figures because the samples were later determined to be acquired from potentially disturbed sediment depths from 32–38 cm in the archive half of core (Supplementary Fig. 10).

Supplementary Figure 13. (a) OxCal Poisson method²³ versus **(b)** linear interpolation method for developing age models of selected $^{231}\text{Pa}/^{230}\text{Th}$ cores that have ^{14}C ages. Error bars represent 2 s.e.m. Triangle and diamond symbols indicate respectively the ^{14}C and non- ^{14}C chronological tie-points of the sediment core age models. Bracketed numbers denote the core identities marked in Supplementary Fig. 1, with references listed in Supplementary Table 1. Bold characters in the figure legend and the square symbols indicate $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study.

Supplementary Figure 14. Sediment reservoir uncertainty in sediment core age models. Age models were developed using several combinations of surface reservoir values derived for high latitudes ($>45^{\circ}$ N) and low latitudes ($<35^{\circ}$ N/S) over the last 25 kyr²⁷: **(a)** maximum surface reservoir values at all sites, **(b)** minimum surface reservoir values at all sites, **(c)** maximum values at eastern high latitudes, minimum values at western high latitudes, and mean values at low latitudes. No changes were made to the age model for the Rockall basin core (50° N, 4.28 km) which was developed using non- ^{14}C chronological tie-points⁹. Triangle and diamond symbols indicate respectively the ^{14}C and non- ^{14}C chronological tie-points of the sediment core age models. Bracketed numbers denote the core identities marked in main text Fig. 1, with references listed in main text Table 1. Bold characters in the figure legend and the square symbols indicate $^{231}\text{Pa}/^{230}\text{Th}$ reconstructions from this study. Error bars represent 2 s.e.m.
