Number of Tables: 2

Number of Texts: 3

Supporting Information includes the following figures, as cross-referenced throughout the main
article:

Text S1 - Comparative performance between Ligands

Text S2 – Synthesis of Al Nanoparticles.

Text S3 - Ligand-modified Al/TiO₂ fabrication.

List of Figures:

Figure S1. **Absorbance spectra of aluminum nanoparticles and Al/TiO₂ heterostructures.**
Ultraviolet–visible absorbance spectra of Al nanoparticles (Al-NPs) dispersed in isopropyl alcohol
(IPA) (a) and Al/TiO₂ heterostructures (b). 4

Figure S2. **Structural and chemical characterization of Al nanoparticles (Al-NPs).** X-ray
photoelectron spectroscopy (XPS) survey spectrum highlighting the presence of Al 2p signals,
with high-resolution Al 2p spectra showing both metallic Al (~71.2 eV) and oxidized Al³⁺ (~74.5
eV), indicating the formation of a thin native oxide shell around the Al cores (a). X-ray diffraction
(XRD) pattern showing characteristic reflections of metallic Al (COD no. 4313206), confirming
crystalline phase formation; absence of Al₂O₃ peaks indicates the amorphous state of alumina
under ambient conditions (b). 5

28	Figure S3. Time-dependent plasmonic absorbance of Al nanoparticles in the UV region.	
29	Ultraviolet (UV) absorbance spectra of Al nanoparticles (Al-NPs) recorded at different time	
30	intervals, showing the evolution of plasmonic properties over time.	5
31	Figure S4. High-resolution transmission electron microscopy (HRTEM) images of Al-NP	
32	cores and Al₂O₃ shells. HRTEM images showing the Al nanoparticle cores and their native Al ₂ O ₃	
33	shells with measured dimensions (a–h). Scale bars: 10 nm (a–f) and 20 nm (g–h).	6
34	Figure S5. Diffraction analysis of Al nanoparticles (Al-NPs). Diffraction patterns of Al-NPs	
35	showing the origin (000) and the (111) planes with (a) and without (b) measurement lines. Intensity	
36	profile extrapolated from the diffraction pattern for calculating the reciprocal interplanar distance	
37	(4.255 nm ⁻¹), corresponding to an interplanar spacing of 0.235 nm (c). The crystallinity of the	
38	synthesized Al-NPs was determined to be 71.4% based on X-ray diffraction (XRD) analysis.	6
39	Figure S6. Transmission electron microscopy (TEM) characterization of Al/TiO₂ Cys. TEM	
40	images of Al/TiO ₂ Cys heterostructures with corresponding fast Fourier transform (FFT) analysis	
41	(a–c). High-resolution TEM (HRTEM) images of panels a and b showing interplanar distances for	
42	Al nanoparticles and P25 TiO ₂ (a*–b*).	7
43	Figure S7. Optical and physicochemical characterization of ligand-modified Al/TiO₂	
44	heterostructures and TiO₂ references. Reflectance spectra as a function of wavelength for	
45	Al/TiO ₂ heterostructures modified with cysteine (Cys), glutathione (GSH), or dimercaptosuccinic	
46	acid (DMSA), Al/TiO ₂ , Cys-modified TiO ₂ , and P25 TiO ₂ (a). Tauc plots used to estimate bandgap	
47	energies (sample concentration: 1000 ppm, 3 mL) (b). Surface charge (zeta potential) and	
48	hydrodynamic size of nanoparticles measured at pH 4–7 and a concentration of 0.003 w/v % (c–d).	
49	Isoelectric point of Al/TiO ₂ Cys and P25 TiO ₂ determined by titration (e).	8
50	Figure S8. Photocatalytic degradation of amaranth and phenol under broadband UV-B	
51	irradiation using ligand-modified Al/TiO₂ heterostructures. Degradation of amaranth (C ₀ = 20	
52	ppm, 20 min) and phenol (C ₀ = 10 ppm, 25 min) under broadband UV-B (280–320 nm, 14.6 W m ⁻²	
53	²) using different ligand-modified Al/TiO ₂ heterostructures.	9
54	Figure S9. Photographs showing amaranth colour change during photocatalytic degradation	
55	using nanoparticles under broadband UV-B irradiation. Images of amaranth (C ₀ = 20 ppm)	
56	recorded from the start to the end of the experiment for each nanoparticle sample under broadband	
57	UV-B (280–320 nm, 14.6 W m ⁻²).	9
58	Figure S10. Photocatalytic degradation of amaranth and phenol under simulated solar	
59	irradiation using ligand-modified Al/TiO₂ heterostructures. Degradation of amaranth (C ₀ = 20	
60	ppm, 20 min) and phenol (C ₀ = 10 ppm, 25 min) using different ligand-modified Al/TiO ₂	
61	heterostructures under simulated solar irradiation (with a UVC filter blocking UV light < 280 nm;	
62	irradiance: 286.26 W m ⁻²).	10
63	Figure S11. Photographs showing amaranth colour change during photocatalytic	
64	degradation under simulated solar irradiation. Images of amaranth (C ₀ = 20 ppm) recorded	

65	from the start to the end of the experiment for each nanoparticle sample under simulated solar	
66	irradiation (with a UVC filter blocking UV light < 280 nm; irradiance: 286.26 W m ⁻²).....	10
67	Figure S12. UV-vis spectra showing photocatalytic degradation of amaranth using Al/TiO₂	
68	Cys and P25 TiO₂. UV-vis absorbance spectra of amaranth (C ₀ = 20 ppm) recorded during	
69	photocatalytic degradation under simulated solar irradiation (with a UVC filter blocking UV light	
70	< 280 nm; irradiance: 286.26 W m ⁻²) and broadband UV-B (280-320 nm, 14.6 W m ⁻²). Panels a-b	
71	show spectra for Al/TiO ₂ Cys, and panels c-d show spectra for P25 TiO ₂	11
72	Figure S13. Physicochemical characterization of Al/TiO₂ Cys, Al/TiO₂, and Cys-modified	
73	TiO₂ to evaluate the effect of phenol on aggregation. Phase analysis light scattering (PALS)	
74	measurements (a), dynamic light scattering (DLS) size distribution (b), and scavenging	
75	experiments performed using 10 mM EDTA and 100 mM isopropyl alcohol (IPA) (c).	13
76	Figure S14. Dark control experiment for amaranth degradation. Photocatalytic degradation of	
77	amaranth (C ₀ = 20 ppm) monitored under dark conditions at room temperature.	13
78	Figure S15. Dark control experiment for phenol degradation. Photocatalytic degradation of	
79	phenol (C ₀ = 10 ppm) monitored under dark conditions at room temperature.	14
80	Figure S16. HRTEM characterization and photocatalytic degradation of amaranth using	
81	Al/TiO₂ Cys and P25 TiO₂. High-resolution transmission electron microscopy (HRTEM) images	
82	showing interplanar distances for Al nanoparticles (0.151 nm and 0.229 nm) and P25 TiO ₂ (0.344	
83	nm and 0.347 nm) at the start of the experiment. Diffraction patterns were used to calculate the	
84	reciprocal of the interplanar distances from intensity versus position graphs. Photocatalytic	
85	degradation of amaranth (C ₀ = 20 ppm) was performed for 20 min under simulated solar irradiation	
86	with a UVC filter blocking UV light < 280 nm (irradiance: 286.26 W m ⁻²).	15
87	Figure S17. HRTEM characterization and photocatalytic performance of Al-NPs and P25	
88	TiO₂. High-resolution transmission electron microscopy (HRTEM) images of (a) Al nanoparticles	
89	(Al-NPs) and (b) P25 TiO ₂ collected at the end of the experiment, showing interplanar distances	
90	of 0.256 nm for Al-NPs and 0.362/0.361 nm for P25 TiO ₂ . Insets: corresponding selected area	
91	electron diffraction (SAED) patterns, with inverse interplanar distances calculated from intensity	
92	versus position plots. (c) Photocatalytic degradation of Amaranth dye (initial concentration 20	
93	ppm) under solar irradiation (286.26 W m ⁻²) for 20 minutes using a UVC filter to block	
94	wavelengths below 280 nm.....	15
95	Figure S18. Electron microscopy of P25 TiO₂. High-angle annular dark-field (HAADF), bright-	
96	-field (BF), and scanning transmission electron microscopy (STEM) images of P25 TiO ₂	
97	nanoparticles. Scale bar: 100 nm.	16
98	Figure S19. X-ray diffraction analysis of P25 TiO₂. Diffraction patterns of P25 TiO ₂ showing	
99	the origin (000) and the (101) lattice planes, with one panel including a measurement line for	
100	reference. An intensity profile extracted from the diffraction pattern was used to calculate the	

reciprocal interplanar distance (2.778 nm^{-1}) and the corresponding interplanar spacing (0.360 nm). XRD analysis indicates a crystallinity of 74% for P25 TiO_2 .

Figure S20. IPA supernatant after centrifugation of ligand-modified and unmodified Al/TiO₂ heterostructures. (a-c) Transparent supernatant from suspensions with ligands, indicating stabilized interactions and effective binding between Al nanoparticles and P25 TiO_2 nanoparticles. (d) Opaque supernatant from suspensions without ligands, showing lack of binding between Al and P25 TiO_2 nanoparticles.

Figure S21. Calibration of Al nanoparticle mass using UV-vis spectrophotometry and ICP-OES. (a) UV-vis calibration curve for synthesized Al nanoparticles. (b) Relationship between absorbance and concentration determined from the area under the UV-vis spectra between 315-325 nm. (c) ICP-OES calibration curve for Al dilution samples measured at the 394.401 nm emission line, using QC 4 as Al standards. Data from ICP-OES were used to validate and calibrate the UV-vis measurements for mass determination of Al nanoparticles.

Figure S22. Irradiation spectra of the light source measured with a radiometer. (a) Solar spectrum recorded with a UVC filter ($<280 \text{ nm}$) showing an intensity of 286.26 W m^{-2} . (b) Broadband UVB spectrum ($280\text{-}320 \text{ nm}$) with an intensity of 14.6 W m^{-2} .

ppm, 3 mL) (b). Surface charge (zeta potential) and hydrodynamic size of nanoparticles measured at pH 4-7 and a concentration of 0.003 w/v % (c-d). Isoelectric point of Al/TiO₂ Cys and P25 TiO₂ determined by titration (e).

Table S1. Characterization of various ligand-modified Al/TiO₂ heterostructures, non-ligand modification and P25 TiO₂

Sample	BET specific surface area m ² /g	Pore diameter (nm)	Eg (eV)	ZetaPotential (V)	Z-Ave d (nm)	Polydispersity index (PDI)
P25 TiO ₂	49.3	28.75	3.27	-15	222.16	0.17
Al/TiO ₂ Cys	44	36	3.27	51	404.79	0.38
Al/TiO ₂ DMSA	39	36	3.32	-12	1675.82	0.37
Al/TiO ₂ GSH	53	36	3.32	30	1655.47	0.4
Al/TiO ₂	47.43	36	3.32	45	387.92	0.37

Figure S8. **Photocatalytic degradation of amaranth and phenol under broadband UV-B irradiation using ligand-modified Al/TiO₂ heterostructures.** Degradation of amaranth ($C_0 = 20$ ppm, 20 min) and phenol ($C_0 = 10$ ppm, 25 min) under broadband UV-B (280-320 nm, 14.6 W m⁻²) using different ligand-modified Al/TiO₂ heterostructures.

Figure S9. **Photographs showing amaranth colour change during photocatalytic degradation using nanoparticles under broadband UV-B irradiation.** Images of amaranth ($C_0 = 20$ ppm)

recorded from the start to the end of the experiment for each nanoparticle sample under broadband UV-B (280-320 nm, 14.6 W m⁻²).

Figure S10. Photocatalytic degradation of amaranth and phenol under simulated solar irradiation using ligand-modified Al/TiO₂ heterostructures. Degradation of amaranth ($C_0 = 20$ ppm, 20 min) and phenol ($C_0 = 10$ ppm, 25 min) using different ligand-modified Al/TiO₂ heterostructures under simulated solar irradiation (with a UVC filter blocking UV light < 280 nm; irradiance: 286.26 W m⁻²).

Figure S11. Photographs showing amaranth colour change during photocatalytic degradation under simulated solar irradiation. Images of amaranth ($C_0 = 20$ ppm) recorded from the start to the end of the experiment for each

nanoparticle sample under simulated solar irradiation (with a UVC filter blocking UV light < 280 nm; irradiance: 286.26 W m⁻²).

Figure S12. UV-vis spectra showing photocatalytic degradation of amaranth using Al/TiO₂ Cys and P25 TiO₂. UV-vis absorbance spectra of amaranth ($C_0 = 20$ ppm) recorded during photocatalytic degradation under simulated solar irradiation (with a UVC filter blocking UV light < 280 nm; irradiance: 286.26 W m⁻²) and broadband UV-B (280-320 nm, 14.6 W m⁻²). Panels a-b show spectra for Al/TiO₂ Cys, and panels c-d show spectra for P25 TiO₂.

Text S1. Comparative performance between Ligands: The photocatalytic performance of Al/TiO₂ heterostructures was evaluated, with Al/TiO₂ Cys demonstrating superior degradation of amaranth and phenol compared to other ligand-modified and non-modified Al/TiO₂ heterostructures. The degradation of both contaminants followed a first-order kinetic model, with high correlation coefficients ($R^2 > 0.99$ for UV-B and >0.90 for solar irradiation). Under solar irradiation, Al/TiO₂ Cys achieved a 71% reduction in amaranth concentration after 20 minutes and a 53% reduction in phenol after 25 minutes, outperforming P25 TiO₂ by 60% for amaranth

degradation and 10.5% for phenol degradation. In contrast, other ligand-modified Al/TiO₂ heterostructures exhibited lower efficiency, with Al/TiO₂ GSH showing particularly poor performance, as shown in SI Fig. S13. The 60% enhancement of Al/TiO₂ Cys compared to the benchmark P25 TiO₂ under simulated sunlight was calculated using the rate constants in the following formula:

$$\% \text{ enhancement} = \frac{v_{Al/TiO_2 \text{ Cys}} - v_{TiO_2}}{v_{TiO_2}} * 100$$

Under UV-B irradiation, Al/TiO₂ Cys again outperformed P25 TiO₂, achieving 98% amaranth degradation after 20 minutes, while performing similarly to P25 TiO₂ in phenol degradation. Other ligand-modified Al/TiO₂ heterostructures showed comparable degradation to P25 TiO₂ for amaranth but negligible degradation for phenol. Cys exhibits stronger coordination with the Al/Al₂O₃ core through its -SH group and with P25 TiO₂ via -NH₂ and -COOH functional groups, as confirmed by ATR-FTIR analysis. Compared to DMSA and GSH, this dual binding enhances the structural stability and facilitates more efficient charge transfer across the Al/TiO₂ interface, leading to improved photocatalytic performance of Al/TiO₂ Cys, particularly toward anionic contaminants.

Table S2. Degradation performance of various ligand-modified Al/TiO₂ heterostructures, non-ligand modification and P25 TiO₂

Sample	% Degradation-UVB		% Degradation-Solar		k-value (min ⁻¹) UVB Degradation		k-value (min ⁻¹) Solar Degradation	
	Amaranth	Phenol	Amaranth	Phenol	Amaranth	Phenol	Amaranth	Phenol
P25 TiO ₂	95.4	99.8	53	49.5	0.1584	0.1293	0.0382	0.0258
Al/TiO ₂ Cys	98	96.2	71	53	0.1998	0.1285	0.0612	0.0285
Al/TiO ₂ DMSA	94	10	65	9.4	0.1434	0.0039	0.0511	0.0046
Al/TiO ₂ GSH	95	-1.3	45	-2.2	0.1608	0.00008	0.0305	0.0008
TiO ₂ Cys	92.5	58.7	49.5	21.9	0.132	0.0371	0.0343	0.0098
Al/TiO ₂	95.3	18.9	52	10	0.1537	0.0076	0.0366	0.0039

Figure S13. **Physicochemical characterization of Al/TiO₂ Cys, Al/TiO₂, and Cys-modified TiO₂ to evaluate the effect of phenol on aggregation.** Phase analysis light scattering (PALS) measurements (a), dynamic light scattering (DLS) size distribution (b), and scavenging experiments performed using 10 mM EDTA and 100 mM isopropyl alcohol (IPA) (c).

Figure S14. **Dark control experiment for amaranth degradation.** Photocatalytic degradation of amaranth (C₀ = 20 ppm) monitored under dark conditions at room temperature.

Figure S15. **Dark control experiment for phenol degradation.** Photocatalytic degradation of phenol ($C_0 = 10$ ppm) monitored under dark conditions at room temperature.

Figure S16. **HRTEM characterization and photocatalytic degradation of amaranth using Al/TiO₂ Cys and P25 TiO₂.** High-resolution transmission electron microscopy (HRTEM) images showing interplanar distances for Al nanoparticles (0.151 nm and 0.229 nm) and P25 TiO₂ (0.344 nm and 0.347 nm) at the start of the experiment. Diffraction patterns were used to calculate the reciprocal of the interplanar distances from intensity versus position graphs. Photocatalytic degradation of amaranth (C₀ = 20 ppm) was performed for 20 min under simulated solar irradiation with a UVC filter blocking UV light < 280 nm (irradiance: 286.26 W m⁻²).

Figure S17. **HRTEM characterization and photocatalytic performance of Al-NPs and P25 TiO₂.** High-resolution transmission electron microscopy (HRTEM) images of (a) Al nanoparticles (Al-NPs) and (b) P25 TiO₂ collected at the end of the experiment, showing interplanar distances of 0.256 nm for Al-NPs and 0.362/0.361 nm for P25 TiO₂. Insets: corresponding selected area electron diffraction (SAED) patterns, with inverse interplanar distances calculated from intensity

versus position plots. (c) Photocatalytic degradation of Amaranth dye (initial concentration 20 ppm) under solar irradiation (286.26 W m^{-2}) for 20 minutes using a UVC filter to block wavelengths below 280 nm.

Figure S18. Electron microscopy of P25 TiO₂. High-angle annular dark-field (HAADF), bright-field (BF), and scanning transmission electron microscopy (STEM) images of P25 TiO₂ nanoparticles. Scale bar: 100 nm.

Figure S19. **X-ray diffraction analysis of P25 TiO₂**. Diffraction patterns of P25 TiO₂ showing the origin (000) and the (101) lattice planes, with one panel including a measurement line for reference. An intensity profile extracted from the diffraction pattern was used to calculate the reciprocal interplanar distance (2.778 nm⁻¹) and the corresponding interplanar spacing (0.360 nm). XRD analysis indicates a crystallinity of 74% for P25 TiO₂.

Text S2. Synthesis of Al Nanoparticles. Aluminum nanoparticles were synthesized in an inert environment using the Schlenk line protocol¹. Nanoparticles were synthesized by the addition of 24 mL of degassed trioctylphosphine in an argon purged Schlenk flask followed by heating at 60°C with vigorous stirring using a metallic block. Next, 6 mL of N, N-dimethylethylamine alane - DMEAA (0.5M in toluene) was added and allowed to stir for 5 minutes. Then, 1.5 mL of Titanium (IV) isopropoxide- TIP (50 mM in toluene) was added to catalyze the decomposition of alane into metallic Al. The reaction mixture turns into a dark, translucent brown color upon the addition of TIP, which gradually changes to an opaque black suspension, indicating the formation of small Al NCs. The reaction was then left to stir for 4 hours at 60 °C under argon flow. Lastly, 10 mL of dibutyl phosphate (50 mM in cyclohexane) was added to end the process. The flask was then opened to air, resulting in the formation of a 3-5 nm, self-limiting, amorphous Al₂O₃ layer at the particle surface. This oxide layer prevents further oxidation of the underlying Al core by air. The nanoparticles were collected through multiple rounds of centrifugation and resuspension in isopropanol. To remove aggregates or large particles, the sample was ultracentrifuged up to 4 times at 10,000xg for 10 mins. For the first 3 washes, the supernatant was discarded, leaving behind the pellet, and for the last wash, the supernatant was collected and diluted for the fabrication of the heterostructures as mentioned in the methods section. UV absorbance characterization of the Al-NPs was performed, and a peak in the UV region was observed. The position and width of the peak varied for each synthesis; however, the absorbance was in the UV region. This could probably be attributed to the size of the nanoparticles in the supernatant from the final centrifuge.

Text S3. Ligand-modified Al/TiO₂ fabrication. Ligands were weighted, 0.01 g of both GSH and DMSA and 0.006 g of Cys, and added to 5 mL of Al-NPs (of conc 67-70 µg/L). The mixture was sonicated for 10 minutes and mixed for 30 minutes. The supernatant was separated from any unmixed ligands, such as Cys, by pouring the supernatant into a different Falcon tube for the next step of the fabrication. 20 mg of P25 TiO₂ was added to the suspension and sonicated for 10 mins, followed by mixing for 30 mins. Following this step, centrifugation was performed to separate the pellet and supernatant.

Figure S20. IPA supernatant after centrifugation of ligand-modified and unmodified Al/TiO₂ heterostructures. (a-c) Transparent supernatant from suspensions with ligands, indicating stabilized interactions and effective binding between Al nanoparticles and P25 TiO₂ nanoparticles. (d) Opaque supernatant from suspensions without ligands, showing lack of binding between Al and P25 TiO₂ nanoparticles.

Figure S21. **Calibration of Al nanoparticle mass using UV-vis spectrophotometry and ICP-OES.** (a) UV-vis calibration curve for synthesized Al nanoparticles. (b) Relationship between absorbance and concentration determined from the area under the UV-vis spectra between 315-325 nm. (c) ICP-OES calibration curve for Al dilution samples measured at the 394.401 nm emission line, using QC 4 as Al standards. Data from ICP-OES were used to validate and calibrate the UV-vis measurements for mass determination of Al nanoparticles.

Figure S22. **Irradiation spectra of the light source measured with a radiometer.** (a) Solar spectrum recorded with a UVC filter (<280 nm) showing an intensity of 286.26 W m^{-2} . (b) Broadband UVB spectrum (280-320 nm) with an intensity of 14.6 W m^{-2} .
