

Supplementary Fig. 2: Dive summary data for 20 adult male Antarctic fur seals instrumented between January and October 2016 at Powell Island in the South Orkney Islands archipelago. Points represent the mean estimate of A) average dive depths and B) maximum dive depths recorded in consecutive 6 hour time periods (00:00-06:00, 06:00-12:00, 12:00-18:00, 18:00 - 00:00). Note the different depth scales. Black curvilinear lines represent daylight length (h) calculated at King George Island. Both average and maximum dive depths were much shallower between January and March, becoming deeper as daylight length decreased into winter..
