

Figure S1: Mean percentages of all nematodes found in the testing arenas which reached the ECs after 6 hours with a fabric of a 300 μ m-mesh size (dark gray) or no fabric (light gray) separating the SCs from the corridor (see Figure 1) with regard to an initial nematode density of 500 and 2500 individuals respectively. The differences between dispersal rates were tested with a t-test (after checking normality of data), n.s.: $p > 0.05$
