DNA Testing Laboratory NGS Report

Date of issue: July 13, 2022
 Prepared by: Nguyen NguyenT.X.
 Approved by: Evgeny Zakharov

CLIENT INFORMATION

Accession number: BIO-22-020
 Client Name: Barbara Frei, PhD; Research Scientist
 Client Address: Urban Ecology & Nature-based Climate Solutions
 Environment and Climate Change Canada
 351, boul. Saint-Joseph, 15th floor Gatineau K1A 0H3
 Contact Name: Barbara Frei (barbara.frei@ec.gc.ca)
 Vanessa Poirier (vanessa.poirier@mail.mcgill.ca)

ITEMS

Description: 56 fecal samples from birds submitted in 15ml and 5ml tubes with ethanol for arthropods (ZBJ-ArtF1c_t1 primers) and plants (ITS2 primers) detection.
 Dates Received: February 10, 2022
 Received From: FedEx (TRK# 2896 1236 9847)
 Dates of Analysis: May 03 – May 26, 2022

METHODS

Fecal samples in 42 15mL-tubes and 14 5mL-tubes were lysed with 500 µL - 2 mL of invertebrate lysis buffer with 2 mg/mL of proteinase K (Promega). DNA was extracted from 50 µL of each homogenate. Extraction was performed using a validated glass fibre, plate-based technique employed by Ivanova, Dewaard, & Hebert (2006) (DOI: 10.1111/j.1471-8286.2006.01428.x). DNA was amplified with arthropod specific primers *ZBJ-ArtF1c_t1/ZBJ-ArtR2_t1* (DOI: 10.1111/j.1755-0998.2010.02920.x) which target a 157 base-pair (bp) fragment of the barcode region of the cytochrome c oxidase subunit I (COI) gene and plant-specific primers *ITS-S2F_t1/ITS4_t1* (DOI:10.1371/journal.pone.0008613), which target an approximate 350 bp fragment of the ITS2 intergenic region. Each DNA extract was amplified twice to achieve two independent PCR and sequencing replicates. PCR results were visualized using pre-cast 2% agarose E-Gels (ThermoFisher). Individual samples were tagged with IonCode universal molecular identifiers (UMIs), and all samples were pooled for sequencing. Size selection was performed on a BluePippin (Sage Science) using a 2% agarose cassette targeting sequences between 200-400 bp (*ZBJ-ArtF1c_t1/ZBJ-ArtR2_t1*) or 250-500 bp (*ITS-S2F_t1/ITS4_t1*). Sequencing was performed on an Ion Torrent S5 sequencer (200 base-read library preparation kit; 200 bp Chef protocol; 510-chip for *ZBJ-ArtF1c_t1/ZBJ-ArtR2_t1* or 400 base-read library preparation kit; 400 bp Ext Chef protocol; 520-chip for *ITS-S2F_t1/ITS4_t1*). Sequencing performance metrics are shown in Figures 1 and 2. The resulting sequence reads were associated to their source sample by the UMIs (with perfect matching), filtered to remove low quality reads (minimum quality of QV20), trimmed to remove primer and adapter sequences (reads lacking a forward primer were excluded from analysis while reads lacking a reverse primer were allowed to proceed to the next step), and then filtered for a minimum size of 100 bp. The processed reads were then compared to a comprehensive BOLD reference library (www.boldsystems.org) and assigned an identity using the BLAST algorithm. The results from BLAST searches were

aggregated into unique taxonomic identifications per sample and identifications were only accepted as genuine if they were supported by at least 100 reads that matched a reference sequence with at least 95% identity across at least 100 bp (Appendices I&II). Further molecular and bioinformatic details are available upon request. All raw data will be privately and securely stored on CCDB servers for at least three months and until storage constraints require deletions of old data. All raw data is available upon request. For methodological reference, please cite Moran *et al*, 2019.

RESULTS

Arthropod detection

As DNA from each sample was amplified two times, there were a total of 112 replicates analyzed (e.g. 1_Rep1; 1_Rep2). The S5 run resulted in over 3M raw reads (Figure 1). A total of 182,603 reads could not be assigned to a known IonCode molecular index and were excluded from all subsequent analyses. The remaining 3,488,127 reads were mapped to one of the wells with either sample DNA template or one of negative controls. The vast majority of the reads were detected in wells with sample DNA (3,264,001), while only 224,126 reads were scored from template-free wells. Arthropod detections were found in 84 replicates out of 112, or 45 out of 56 samples for replicate 1 and 39 out of 56 samples for replicate 2 (Appendix I). Detected arthropod items represented approximately 195 species belonging to 76 families and 13 orders. The most commonly detected orders were Lepidoptera, Diptera, and Araneae (Figure 3 and 4). Each detection was supported by an average of 1340 sequence reads.

Plant detection

The S5 run resulted in over 5M raw read (Figure 2). A total of 440,404 reads could not be assigned to a known IonCode molecular index and were excluded from all subsequent analyses. The remaining 4,577,170 reads were mapped to one of the wells with either sample DNA template or one of negative controls. The vast majority of the reads were detected in wells with sample DNA (4,107,793), while 469,377 reads were scored from template-free wells. Plant detections were found in 75 replicates out of 112, or 37 out of 56 samples for replicate 1 and 38 out of 56 samples for replicate 2 (Appendix II). Approximately 56% of the plant sequences recovered from all replicates showed no significant similarity to any of the publicly available records on BOLD and were thus assigned an identity of “unknown”. Detected plant items (i.e. those that could be identified) represented approximately 62 species belonging to 28 families and 18 orders. The most commonly detected orders were Rosales, Ericales, and Fagales (Figure 3 and 4). Each detection was supported by an average of 1443 sequence reads.

INTERPRETATION

While many identities are listed to species (Appendix I and II), we recommend only considering identifications reliable to the level of genus due to the short length of the molecular markers used. We do not recommend using read counts as a measure for prey abundance, but rather as a guide for the reliability of detection (i.e., the more reads upon which a detection is based, the more confident you can be in that detection). The negative controls did not produce identifiable sequence reads, suggesting that the results presented here were not compromised by laboratory-introduced contamination.
