

For the LbcA and PA1198 immunoblots

The ECL only file was used to generate the figure. The lower LbcA-specific bands are likely to be truncated LbcA proteins that become visible when LbcA is encoded on a plasmid. The most abundant band corresponding to full length LbcA was used for the figure, as boxed.

The ECL+visual overlay image is also included because it also shows the visual appearance/size of the membrane piece used for each western.

Protein

This single membrane was used for both the LbcA immunoblot (top section) and PA1198 immunoblot (bottom section). Therefore, a single section as indicated was used from this membrane to show protein loading in the figure.
