

Figure 5c Platelet Count at End of Study. Both the 7-round and 1-round groups are plotted together, as the results were similar, although there was slightly more decrease for the 7-round than the 1-round group. The primary effect of DMSA is to normalize elevated or (in one case) low platelets. One child still has a high value of 1195 k/mm³ which is not shown, but it has decreased substantially from its initial value of 1996 k/mm³).
