

Supplementary Figure S1. A comparison of auxin concentration on total mean area of callus induced after 35 days. Populations and days were analyzed separately under a one-way ANOVA controlling for auxin. ANOVA test showed differences among treatments for both HAL2 and FIL2 populations ($p < 0.01$). Mean separation was analyzed with **Tukey's Honest Significant Difference (HSD)**. These data represent three replicates of 33 callus pieces per replicate.
