
Additional file 6: Renin concentrations regarding doses of norepinephrine among transfused patients.

Evolution of renin concentrations over 48 hours following severe trauma admission regarding norepinephrine doses at the different time points in patients presenting hemorrhage (light blue= low dose of norepinephrine, dark blue= high dose of norepinephrine).

Hemorrhage was defined as the transfusion of at least one pack of red blood cells (pRBC) during the first 6 hours after admission. Patients were split at each time point according to norepinephrine doses at this one. Comparison between groups at each time points are presented. * indicates P<0.05, ** indicates P<0.01 *** indicates P<0.001. All values are presented as the median, interquartile range and 10-90th percentile.
