Comparison of the dissemination rates of dengue virus serotypes in each mosquito species and colony.

The dissemination rate of dengue virus (DENV) serotypes for each mosquito species and colony is shown in bar graphs, which was determined by detecting DENV RNA from the head, wings, and legs of individual mosquitoes 14 days after feeding on blood containing the virus. A, B, and C show results for the *Aedes aegypti* (Aae) HCM and *Ae. albopictus* (Aal) IKT and BSD colonies, respectively. Error bars represent the 95% confidence interval. Statistical analyses were performed by Fisher's exact test with Holm-Bonferroni correction. Statistically significant differences ($P < 0.01$) between DENV serotypes are indicated by letters (a, b, c, ab, or ac). Serotypes with the same letter in each graph are not significantly different.
